FRACTURE OF THE OLECRANON PROCESS OF THE ULNA

Treatment by Excision of Fragment and Repair of Triceps Tendon

Chairman's Address

FRANCIS M. McKEEVER, M.D.
Los Angeles
and
RONALD M. BUCK, M.D.
St. Joseph, Mo.

Fracture of the olecranon process of the ulna not infrequently results in some degree of loss of flexion and extension of the elbow joint. Particularly is this so in elderly persons and in patients subjected to long immobilization with the elbow in extension. So prolonged is the recovery from treatment by immobilization in extension that this treatment has been almost abandoned. Open reduction and fixation of the fractured fragment to the shaft of the ulna in order to permit early mobilization of the elbow has superseded the closed method of treatment. Many different types of suture, including catgut, wire and fascia, have been advised and many ingenious screws for fixation of the olecranon fragment have been devised.

Even with these types of treatment, which permit relatively early mobilization of the joint, some loss of motion is the rule in the older patient, and is not infrequent in younger patients. After suture, with whatever material it is accomplished, the complication of separation of the fragments due to rupture of the retention suture is not uncommon. Even though the suture remains intact, the olecranon fragment too often tilts a little, resulting in an incongruous articular surface which eventually causes a traumatic arthritis of the elbow joint. Extensively comminuted fractures of the olecranon do not lend themselves well to any type of internal fixation, and a congruous joint surface cannot be restored.

Removal of the fractured fragment of the olecranon does away with the necessity for the healing of a fracture, which is time consuming and necessitates long immobilization in a joint which does not tolerate fixation well. It obviates the necessity to heal a bone and substitutes only the necessity to heal fascia, thus shortening the time of fixation of the joint. It also obviates the chance for an incongruous articular surface.

Excision of the fractured fragment is not applicable before the completion of bone growth. It should not be done in those rare instances in childhood and adolescence in which the upper epiphysis of the ulna is separated from the shaft, as a growth disturbance is certain to result. Any fragment with an epiphysis attached should be replaced.

Excision of the fractured fragment in treatment of fractures of the olecranon has not received prominence in the literature. In 1918 Foille[1] reported the treatment of 1 patient by this method. Although we are certain that this type of treatment has been employed by many surgeons in the United States, there are no reported series in the literature from this country. Dunn[2] in England in 1937 reported 2 cases in which he employed this type of treatment and stated that the early return of good function was so striking that he had performed his last suture of the fragments. Wainwright[3] in 1942 reported the end results of 20 fractures of the olecranon treated by this method and felt it superior to attempts to effect union in older persons and in comminuted fractures. He also felt it acceptable in young persons when hasty return to work was necessary.

Our purpose in this paper is (1) to present the end results of treatment of fractures of the olecranon process of the ulna by total excision of the fractured fragment in 10 patients, (2) to enumerate the indications for this type of treatment and (3) to present a technic for excision of the olecranon process and repair of the triceps tendon.

Excision of the olecranon process was performed on 7 patients with old ununited fractures of the olecranon. Five of these patients had previously had an open reduction and fixation of the fragments with a wire loop. In 2 of these patients the wire loop had ruptured with separation of the fragments and in 3 the wire loop had stretched enough to permit a hiatus between the fragments with a nonunion. Two patients who had suffered compound fractures had been debrided and immobilized without any internal fixation. All had a complete nonunion and an incongruous articular surface. The excision of the fragment was carried out on an average of seven and one-half months after the original injury in these patients. The shortest interval between the injury and excision of the fragment was five months, and the longest interval was thirteen months. All patients prior to excision of the fragment complained of pain and all presented restriction of

motion in the elbow joint. The average restriction of flexion of the elbow in these 7 patients was 38 degrees. One patient had a restriction of flexion of 55 degrees, and 1 had lost only 10 degrees of flexion. The average loss of extension in these 7 elbows was 28 degrees. One patient had lost no extension, and the greatest loss of extension was 60 degrees.

In all patients subjected to this procedure there was a decrease in the subjective complaint of pain after the operation. All patients had an increase in the range of motion of the elbow joint as a result of the operation. The average improvement in motion in these 7 patients was 57 degrees. The greatest improvement in motion was in a patient who obtained an increase of 90 degrees, gaining 50 degrees in flexion and 40 degrees in extension. The least improved patient was a person who gained only 10 degrees of motion. This patient had, however, only a 10 degree restriction of flexion to start with and regained normal flexion with a relief of pain and improvement in strength.

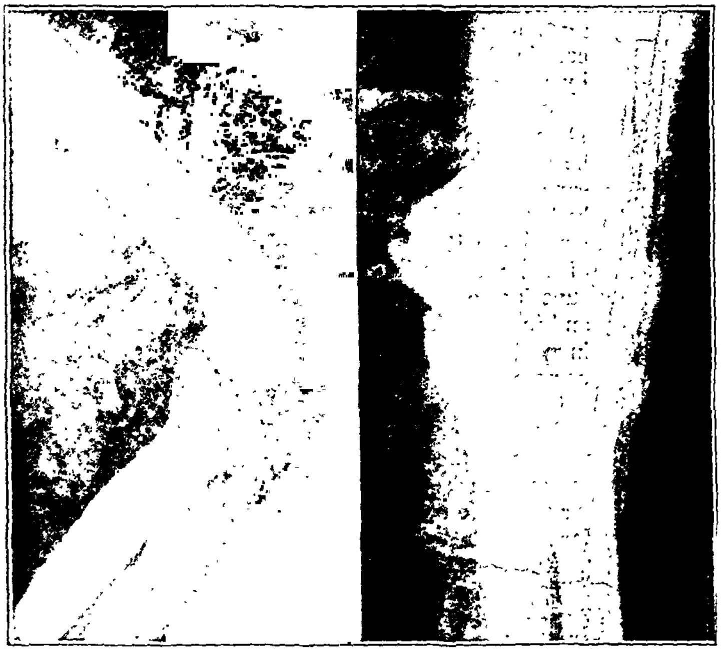

Fig. 1 (W.G.).—Postoperative appearance after removal of fragments and tricepsplasty.

The gain in motion after operation, moreover, was rapid. In all instances 60 to 70 per cent of the restored motion resulted in the first sixty days after operation.

Three of these patients had normal strength in the triceps muscle and were able to do push-ups from the floor. Four patients lost some strength in the ability to extend the elbow against resistance. The greatest loss of triceps power amounted to 25 per cent, which would be disabling only for prolonged, repeated overhead lifting.

Three patients felt that they traumatized their ulnar nerve, or "bumped their crazy bone," easier than before the excision of the olecranon. The other four noticed no tendency to strike the "crazy bone." None had any subjective or objective neurologic complaints referable to the ulnar nerve distribution in the hand. It is probable that the anterior transposition of the ulnar nerve should be done at the time of excision of the olecranon. This can be easily carried out, as the nerve should be isolated at the time of the excision and tricepsplasty.

One patient with a large fragment broken out of the olecranon process, which did not enter the trochlear (semilunar) notch, was treated by excision of the fragment and repair of the rent in the triceps tendon. This patient promptly, within four weeks, regained a normal range of motion in the elbow joint. This type of fracture should always be treated by excision of the fragment. Such fragments are prone to nonunion and remain loose and painful.

One patient, who suffered a severely comminuted fracture of the olecranon process, caused by severe direct trauma to the joint, was treated by excision of the comminuted fragments and repair of the tendon. The fragments which were removed comprised 70 per cent of the trochlear (semilunar) notch. Because of infected lacerations on the skin, resulting at the time of injury, excision of the fragments had to be delayed for seven weeks, until the skin healed and no longer carried the danger of infecting the elbow joint. During these seven weeks the elbow was immobilized except for dressings. At operation there was advanced organization of the comminuted fragments, and any attempt at suture was impossible. Six months after excision of the fragments and repair of the triceps tendon the patient had 110 degrees of motion in the elbow joint. He was restricted only 5 degrees in flexion and 25 degrees in extension. There was no weakness in the triceps muscle, the patient being able to do push-ups from the floor. He had no complaints referable to the ulnar nerve (figs. 1, 2, 3 and 4).

In 1 patient, a housemaid aged 60, an acute fracture of the olecranon process was treated by excision of the fragment and repair of the tendon. In this patient the fragment comprised one half of the trochlear (semilunar) notch of the ulna. Sixty days after the operation the patient returned to her duties as a maid and had 110 degrees of motion in the elbow. Six months after the excision of the fragment, she had a normal range of flexion and extension in the elbow joint, normal strength in the triceps muscle and no complaints.

Instability of the elbow joint does not result from this procedure as long as the coronoid process and the vertical distal face of the trochlear (semilunar) notch of the ulna remain. Stability of the elbow joint is dependent on the coronoid process and the distal vertical face of the ulna, the lateral ligaments of the joint and the function of the biceps, brachialis and triceps muscles. If the fracture of the ulna is distal to the coronoid process the fragment should not be excised. Removal of a fragment of this size amounts to a partial resection of the elbow joint. When the fracture is proximal to the coronoid process, a fragment which constitutes 80 per cent of the trochlear (semilunar) notch of the ulna may be excised and result in absolutely no loss in the stability of the elbow joint.

TECHNIC OF OPERATION

A curved skin incision, starting on the forearm 10 cm. below the tip of the olecranon and extending 10 cm. up the arm from the tip of the olecranon, is made through the skin and fascia. The incision is made to deviate to the medial side of the olecranon process. The skin and subcutaneous tissue on the posterior aspect of the elbow are reflected widely to the medial and lateral sides to give good exposure of the condyles of the humerus. The ulnar nerve is isolated and freed adequately to permit of its transposition to the front of the medial epicondyle of the humerus. The nerve is protected throughout the operation.

This exposes, in the arm portion of the incision the lower tendinous portion of the triceps and medially some of its muscle fibers. On the lateral side the border of the triceps and the fibers of the extensor carpi radialis muscle are in view. In the lower or forearm portion of the incision the tricipital aponeurosis and the fibers of the origin of the flexor carpi ulnaris are exposed. On the lateral side the tricipital aponeurosis blends with the dense fascia covering the anconeus.

Starting over the ulna, 2 to 3 cm. distal to the fracture line through the olecranon process, a tongue of fascia, aponeurosis and periosteum of the ulna is cut with a sharp knife. The end of this tongue should be 3 to 3.5 cm. wide. The lateral margin of this tongue is cut through the fascia covering the anconeus and as far proximally as the fibers of the extensor carpi radialis. The medial side of the tongue is cut through the tendinous portion of the triceps to the point where it deviates laterally and then extends 2 cm. into the muscle fibers. The tongue is freed by pushing the periosteum off the ulna with a sharp elevator up to the point of fracture. Any remaining attachments of the sides of the tongue are then freed by sharp dissection. This permits the tongue to be turned over on itself with the fractured fragment, or fragments, attached to it and completely exposed. The humeral surface of the elbow joint is also widely exposed so that any fragments of abraded articular cartilage on the trochlear and capitellum may be removed.

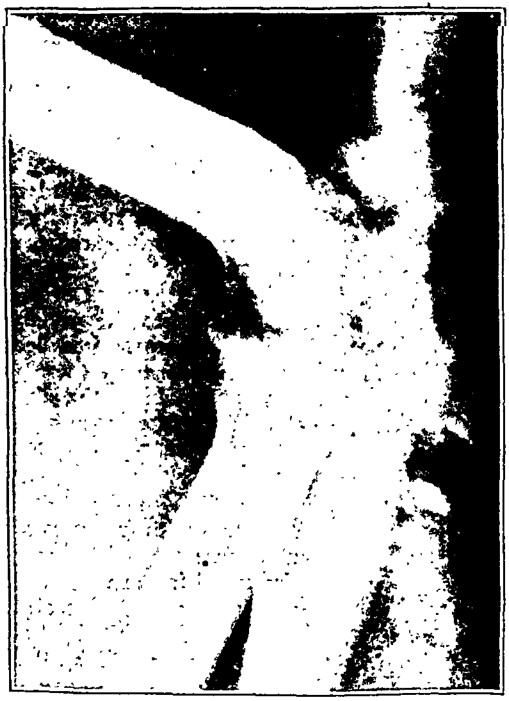

Fig. 2.—Preoperative appearance of extensively comminuted fracture of olecranon in patient W. G.

The fractured fragment is then removed from the tongue of aponeurosis by sharp dissection with a knife, cutting close to bone. If this is done carefully, the aponeurosis will not be buttonholed. In fresh fractures there may already be a large rent in the aponeurosis. In old ununited fractures there is a thick, dense band of scar completely covering the fragment, and the fractured piece of bone can be easily removed without perforating the tongue. This leaves a dense fibrous tongue of aponeurosis which can, by gentle traction, be stretched as much as 1.5 cm., owing to the fact that its sides extend into muscle fibers and the free lateral border of the triceps. The proximal end of the ulna is then smoothed by removing any sharp spicules which may project from its cortex.

Fig. 3 (W. G.).—Range of motion in flexion and extension of elbow six months after excision of fragments and tricepsplasty.

The edge of the periosteum of the ulna from which the tongue has been released is then elevated enough to create an edge to which the aponeurotic tongue may be sutured. If desired, the periosteum of the ulna may be incised 1 or 2 cm. distal to its proximal edge, thus creating a tunnel to pass the end of the tongue beneath.

With the elbow extended, gentle traction is made on the tongue, which causes it to slide in relation to the lateral and medial structures from which it has been separated. A few sutures of number 0 chromic catgut passed through the sides of the tongue while it is held under tension, into the lateral and medial fascial structures from which it was freed, tend to hold it stretched and reduce the muscle pull of the triceps.

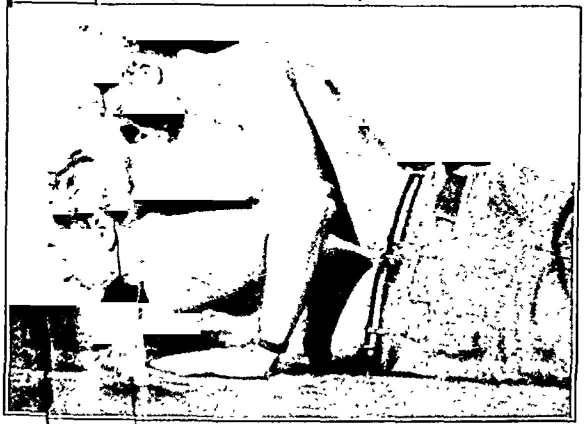

Fig. 4 (W. G.).—Elbow during push-ups, showing preservation of triceps power.

The distal end of the tongue is then sutured about its periphery to the elevated proximal end of the periosteum and fascia over the ulna, with interrupted sutures of number 0 chromic catgut. It may be overlapped and imbricated. If a tunnel of periosteum has been created it is passed under the tunnel and sutured to the periosteum and fascia distal to the tunnel, and

ttress sutures are placed through the roof of the

Fig. 6.—Technic of operation: *D*, removal of fragment by sharp lissection; *E*, elbow extended to reattach triceps to ulna; *F*, suture of tongue of triceps aponeurosis to periosteum of ulna; *G*, skin closure and position of immobilization.

Before the skin is closed, the extended elbow is flexed to note the tension on the tongue. It is usually possible to flex the elbow to at least 110 degrees (through 70 degrees) without producing undue tension on the sutures holding the tongue to the periosteum. The skin is then closed by approximating its edges with interrupted sutures of fine silk. The suture line is covered with petrolatum gauze and dressings. The arm is copiously bandaged with sterile sheet wadding. A molded plaster splint is applied along the posterior aspect of the arm and forearm from the axilla to the wrist, with the elbow flexed to an angle which does not put undue tension on the sutures holding the tongue, usually 70 to 90 degrees.

The immobilization is continued for three weeks and then the splint is discarded and motion started. After the splint has been discarded the patient may carry the arm in a sling for a week to ten days.

In fresh fractures there may be, and usually is, a rent of varying size in the aponeurosis. Even though a rent is present, a tongue of triceps aponeurosis can be developed which permits of adequate attachment to the surrounding structures to give good anchorage of the triceps muscle to the ulna. If the suture of the triceps aponeurosis to the periosteum of the ulna is compromised because of the presence of a rent, it may be necessary to immobilize the elbow in a greater degree of extension than if a complete tongue of aponeurosis is available.

SUMMARY

Ten patients with fractures of the olecranon were treated by excision of the fractured fragment and repair of the triceps tendon. Five of these patients had old ununited fractures of the olecranon in which attempts to obtain union of the fragments by open reduction and suture with wire had failed. Two patients had an ununited fracture, which resulted from the treatment of a compound fracture by simple immobilization following débridement. One patient had an extensively comminuted fracture for which operative intervention had to be delayed two months because of infected skin. One patient had a fresh fracture, and 1 patient had a fracture which did not enter the trochlear (semilunar) notch.

All patients with old ununited fractures of the olecranon gained motion following this procedure Three patients with old ununited fractures had normal power in the triceps, and 4 patients had 75 per cent of normal power in the triceps. Of these 7 patients with old ununited fractures treated by excision of the fragment, 3 felt that their "crazy bone" was more vulnerable than before the operation. None had any instability of the elbow. All had returned to various kinds of gainful occupation. The most severe complaint consisted of an ache after prolonged heavy work.

One patient with an extensively comminuted fracture treated in this manner regained 110 degrees of motion in the elbow and normal strength in the triceps and had no complaints. An elderly patient with a fresh fracture treated by excision of the fragment and repair of the triceps tendon regained normal motion and normal triceps power and returned to her work as a maid in sixty days.

Excision of a fragment which did not involve the joint in 1 patient resulted in a normal elbow.

CONCLUSIONS

1. Old ununited fractures of the olecranon process of the ulna should be treated by excision of the fragment and repair of the triceps tendon.

2. Attempts to obtain union of old ununited fractures of the olecranon process by bone grafting requires long immobilization and results in severe loss of motion in the elbow. These fractures should not be treated by bone grafting.

3. Extensively comminuted fractures of the olecranon process of the ulna should be treated by excision of the fragments and repair of the triceps tendon.

4. In elderly people with acute fractures of the olecranon excellent results can be expected from treatment by excision of the fragment and repair of the triceps tendon.

5. Any fragment fractured from the olecranon process which does not involve the trochlear notch should be removed.

6. Instability of the elbow joint will not result as long as the coronoid process and the distal face of the trochlear (semilunar) notch of the ulna remain. As much as 80 per cent of the trochlear (semilunar) notch may be removed without danger of producing instability in the elbow joint.

7. Severe loss of triceps power does not result from excision of large fragments of the olecranon.

Medical Rehabilitation.—Now let's take a look at medical rehabilitation which is made up of five different divisions: physical therapy, occupational therapy, corrective therapy, educational therapy and manual arts therapy. They're all part of the VA program. They help patients to build up within themselves the will and the morale to get out of bed, to learn to stand, to dress, to operate a wheelchair, to walk—to want to get well. They help patients to start thinking about future job possibilities. They help patients to devote serious thought and serious effort to the kind of work they'd like to do later on, the kind of work they may be physically fitted to do. And they start doing this as soon as the patient enters the hospital. Along with this physical therapy, educational therapy goes hand in hand. Sixty-five per cent of our enlisted men in World War II and 13 per cent of our officers never graduated from high school. With the help of educational therapy we have provided the added driving force that made it possible already for 2,000 disabled veterans to win high school diplomas. . . .

I don't want you to get the idea that the purpose of medical rehabilitation is to help get a veteran through high school and send him on to college or to train him for a job. We do that in many cases. But the primary purpose of medical rehabilitation is to help a patient get well faster.—Excerpt from address by Dr. Paul R. Hawley before the twenty-sixth National Convention of Disabled American Veterans, 1947.

DELAY IN THE DIAGNOSIS OF CANCER

JOHN E. LEACH, M.D.
and
GUY F. ROBBINS, M.D.
New York

Theoretically, all cancers would be curable if the diagnosis were made quickly enough and the proper treatment were applied immediately. Because in some sites the disease may be insidious in onset and so protean in its early symptomatology, this goal will never be reached until the cause of cancer is determined or until the universal cure for cancer is found. With all the advances made in the diagnosis and treatment of cancer in the last twenty-five years, it is a fact that the reduction of cancer mortality, potentially possible, has hardly begun. The primary reason for this failure is not due to inadequate therapeutic measures. The basic cause for the lack of improvement is the prolonged delay between the time when the patient has first symptoms and the time when definitive treatment begins.

In Dorn's[1] recent survey it has been estimated that there are 300,000 new cases of cancer annually in the United States. Each year about 150,000 persons die of this disease. He has estimated further that 34 per cent of all the patients in whom a diagnosis of cancer is made die within one year. Five year survival rates in unselected cancer patients run considerably lower. On the other hand, five year survival rates in patients treated for early cancer are much higher—approximately 75 per cent in cancer of the breast and exceeding 95 per cent in cancer of the lip. The responsibility for the failure in improvement of cancer mortality rates lies both with patients and physicians. Yet reduction in the delay in diagnosis is the one point in the current offensive against cancer that holds more immediate promise than any other associated clinical or research activity at the present time.

In 1938 Pack and Gallo[2] surveyed 1,000 cases of cancer and determined where the culpability for the delay in the diagnosis of cancer lay—the physician, the patient or both, and to what extent. Since many of their data were drawn from Memorial Hospital files, it seemed a logical step to make a similar survey at the same hospital. This was done in the first three months of 1946.

The objectives of the study were to determine the present status of the delay and culpability and to determine if any progress had been made since the period 1923-1938, the time covered in the previous study.

METHOD OF STUDY

The method of study was relatively simple. All new clinic cancer patients, suspected or proved, were first seen in the examining clinic of the hospital. Here an initial complete history and physical examination were made. The data used in this study were obtained by physicians, and the patients were not aware that a special study was being made. Actually, the questions asked were no different than those asked in any complete history, consisting of: When did you first have symptoms? When did you first consult a physician?

From the Medical Department, Memorial
Physician (Dr. Leach) and National Cancer

[1] Dorn, H. F.: Illness from Cancer in the
Rep. **59**: 33 (Jan. 14); 65 (Jan. 21); 97

[2] Pack, G. T., and Gallo, J. S.:
ment of Cancer, Am. J. Cancer **33**: 44

How soon after you first consulted a physician was treatment started? Was a piece of tissue removed for examination? Of what did the treatment consist? and the like. Five hundred random case histories were used. The data were abstracted to special forms for recording and analysis.

In order to make the study as similar to the prior survey as possible, the ground rules used for determining delay and culpability were those set up by Pack and Gallo. These are:

1. The patient was considered at fault if: (*a*) he delayed three months or more after first symptoms until he consulted a physician or (*b*) he refused to follow acceptable advice such as a biopsy, roentgen studies or referral to a suitable person, hospital or clinic.

2. The physician was considered culpable if: (*a*) he failed to arrive at a diagnosis in a month or, if unable to do so, did not refer the patient to a suitable person, hospital or clinic; (*b*) he failed to give proper advice or any counsel at all, or if he failed to apply proper therapeutic measures, or (*c*) he failed to refer the patient to a suitable person, hospital or clinic when the patient failed to improve.

3. Naturally, if a combination of the above factors as present, the physician and the patient were condered jointly responsible for the delay.

Delay and Culpability

	Pack & Gallo[2] %	Present Study %
Patient alone	44.3	32.0
Patient and physician	18.0	10.8
Physician alone	17.0	27.8
No delay	20.7	29.4
	100.0	100.0

It is appreciated that data obtained from the patient alone are biased. A patient coming to a known cancer clinic is often frightened and on the defensive. He may try to justify his unhappy situation by rationalization. Too often he minimizes his negligence and magnifies his physician's errors, actual or presumed. He will forget the good advice he received and recall the unsound. Sometimes he will actually lie, possibly trying to obtain sympathy or special benefits of one type or another. However, the survey made by Pack and Gallo in 1938 contained similarly biased statements, since their data were obtained from case histories. Since this and the previous study are biased in the same direction, i. e. in favor of the patient and to the physician's disadvantage, they cannot represent the whole truth. But comparisons made on such data are quite valid.

Mention must also be made that the results in this study are not necessarily a cross section of cancer patients in this metropolitan area. The distribution of cancer by anatomic site in patients at Memorial Hospital is not the same as for the general population. Moreover, during the period in which this study was made, the Memorial Hospital was conducting a special drive for funds, with its attendant publicity. The latter must necessarily have had some effect on making the public temporarily more cancer conscious. This probably has decreased the patient responsibility and comparatively increased the physicians' responsibility for delay.

RESULTS

The data were first broken down into overall delay and culpability, as shown in the accompanying table.

It is evident that there has been a sizable decrease in delay on the part of the patients, whether considered by themselves or in conjunction with the group "patient and physician." On the other hand, the culpability of the physician alone has increased appreciably. If one considers this latter group with that of "patient and physician," i. e., cases in which the physician was responsible for delay either alone or in part, there has been a slight apparent increase from 35 to 38.6 per cent—actually of no statistical significance; at least there has been no improvement. The improvement in the "no delay" group from 20.7 to 29.4 per cent is wholly due to the decrease of the "patient alone" category from 1923-1938 to 1946. Stated in another manner, the patient is seeking help earlier but the physician does not appear to be taking advantage of the improved opportunity.

It was evident to those of us working in the examining clinic, even before this study was instituted, that many of the patients who had consulted a physician had not received an adequate examination. In order to see how much this was a factor in delay and in culpability, the cases were then broken down into four groups:

1. *Superficial.*—The superficial group consisted of those cancers that could be detected or suspected by a superficial examination. Examples of this group are cancer of the skin, lip, anterior part of the tongue and the like. One third of the group consisted of cancer of the skin.

2. *Breast.*—Cancers of the breast were placed in a separate category chiefly because of the publicity given to this form of cancer in the past.

3. *Thorough.*—The thorough group consisted of those cancers that could be detected or suspected by a careful history and complete physical examination. Examples of this are cancer of the floor of the mouth; of the posterior two thirds of the tongue; gynecologic cancer; cancer of the distal rectum and anus, and malignant lymphomas.

4. *Special.*—The special group consisted of those cancers that could be detected or suspected by a careful history and complete physical examination plus roentgenographic or endoscopic studies or both. Examples of this group are cancer of the lung, esophagus, stomach, upper rectum and colon; cancer of the kidney and bladder.

These data are portrayed in chart 1. This analysis is decidedly provocative and shows the following distinct trend: As one progresses from the superficial group, in which a lesion should be fairly obvious (if not to the patient at least to the physician) to the thorough and special groups, in which a more searching examination or special diagnostic studies are required to arrive at a diagnosis, the patient becomes decreasingly culpable while the blame assessable to the physician increases. Considered overall, the combined blame—"the physician and patient"—remains rather small in all the groups. The variations of the "no delay" category from group to group are interesting.

In almost one half of the breast cases (42.1 per cent) there was no delay. This suggests that the publicity given to cancer of the breast is affecting a large audience. The delay in patients with superficial lesions is high and not surprising to those working in the field of cancer. The seemingly innocuous, painless cancer of the skin or lip that can be observed daily seems to cause little concern until finally for a variety of reasons (cosmetic, annoyance, repeated bleeding, pain or advice of friends or relatives, or the like) the patient will seek medical aid. Oddly enough, he may then be dismayed at the diagnosis of cancer and may resent being discommoded by the therapy. In this group the physicians' culpability is low and essentially the same as in the breast group.

Undoubtedly there are cases in the special group in which the first physician suggested that special diagnostic studies be carried out or that the patient be referred to a suitable hospital or clinic although this was refused or the suggestions were not carried out. During the period of this study there was still an unfavorable wartime ratio of physicians to patients. Those patients who had to depend on hospital clinics often found them overworked and understaffed and their laboratories in a similar position. These are factors—impossible to measure—that tend to mitigate the physician's poor showing to some extent.

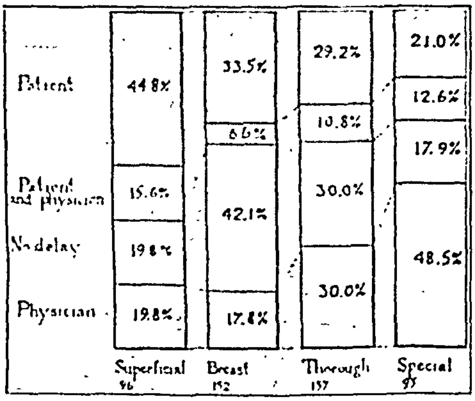

Chart 1.—Responsibility for delay in the diagnosis of cancer.

The data were then analyzed to determine the cause for delay among physicians—whether solely or partly responsible. There were 193 such instances. They are illustrated in chart 2.

Although each group is relatively small, several points may be made:

1. A good segment of the patients received improper treatment, judged by modern average standards.

2. Almost one half of the patients with cancer of the breast received improper advice. The usual purport of this was "If it doesn't bother you, don't bother it (the tumor)."

3. In almost one half of the cases in the special group there was an undue delay in making the diagnosis. Much of this was due to the assumption that the patient had a functional disorder or a benign disease. Many physicians are still unaware that early cancer in a relatively inaccessible part of the body can imitate a wide variety of functional and benign disorders. Many are still thinking in terms of the symptomatologic manifestations of late cancer.

The data were then analyzed in terms of delay in months between first symptoms and the start of treatment. This material did not permit the division into the three logical steps of first symptoms to first physician, first physician to diagnosis and diagnosis to therapy. However, the data were such that an accurate segregation into first symptoms to first physician and first physician to therapy could be made. They were analyzed by groups as described before. Five hundred cases of cancer are too few for averages to be significant because the time ranges are too great; hence, median times were used. Unfortunately, these latter measures are not comparable statistically, but at least they suggest trends. They are shown in chart 3.

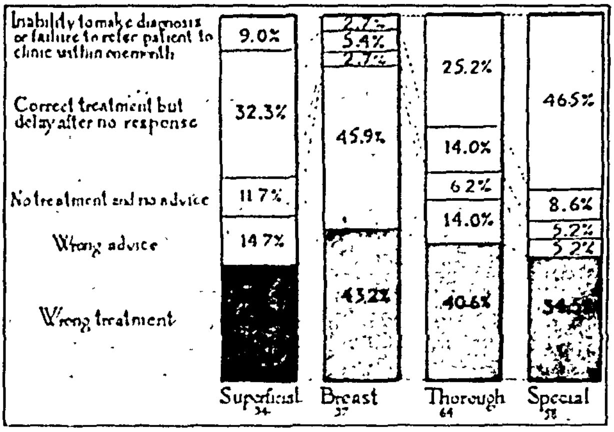

Chart 2.—Why did physicians delay?

It may be seen that as one progresses from a superficial lesion to one that is not so apparent, the delay in time on the part of the patient decreases, while that of the physician increases. This confirms the data depicted in chart 2. It should be called to mind that a median is a 50 per cent level. These data convey two ideas: the delay in time was not only quite long in the better half of the group shown, but also, in the other 50 per cent the delay was even greater.

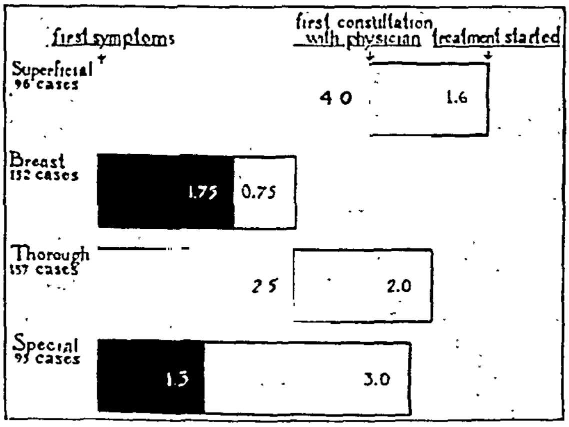

Chart 3.—The lapse of time between first symptoms and the start of definite treatment. The figures indicate the median time in months.

COMMENT

These data are not submitted to draw criticism to the medical profession's role in the f[illegible] against cancer. Errors in judgment, in diagnosi[illegible] therapy [illegible] made by everyone. As long [illegible] dical [illegible] remains a dynamic combinatio[illegible] nd scien[illegible] will continue. [illegible] y of t[illegible] tton [illegible] is a long way [illegible] the [illegible] st for tonsillectomy cases[6] have been included because the data on the interval between operation and the onset of symptoms seem pertinent in several ways. They resemble the figures based on contact with known cases, and they suggest that the natural incubation period is not shorter than the post-tonsillectomy period.

The possible wide variation in these figures—ranging from a few days to three to five weeks—raises the question as to how, in a given group of presumably related cases, the primary and secondary cases are to be identified. It could even be expected that in some instances the actual primary case will not be the first one to exhibit the clinical disease; and conversely, the first apparent case may actually be secondary to a case which does not show clinical signs until some later date. In fact, the report by Brown, Francis and Pearson[7] of the detection of virus in the stools of a boy nineteen days before he manifested paralytic poliomyelitis makes it conceivable that a family or community outbreak lasting several weeks could be due entirely to exposure of all patients at the same time.

The difficulty in evaluating the incubation period in human poliomyelitis arises in part because the clinical course is variegated and there is no uniform interpretation among clinicians as to which is the first day of disease. Figure 1 illustrates the more commonly observed clinical forms. It is estimated that 80 per cent of the patients exhibit only mild and brief symptoms: their illnesses are so slight that many are never even seen by a physician.[8] The remaining 20 per cent, the frank cases, comprise the majority of those which are diagnosed poliomyelitis. About half of these have a diphasic "dromedary" course indicated as *A* in figure 1. In this form of the disease there is a brief, preliminary first phase illness characterized by nonspecific symptoms—fever, sore throat, vomiting and headache. Then follows a period of well-being lasting from one to four days or even as long as a week or more, and later, the appearance of the second phase, in which there is again fever and for the first time clinical evidence of involvement of the central nervous system—stiff neck, stiff back, sometimes reflex changes and paralyses. The frequency with which the various symptoms occur in the two phases is shown in figure 2. The occurrence of sore throat as a prominent first phase symptom and its comparative rarity in the second phase may even have some diagnostic value in determining the stage of the disease with which one is dealing.

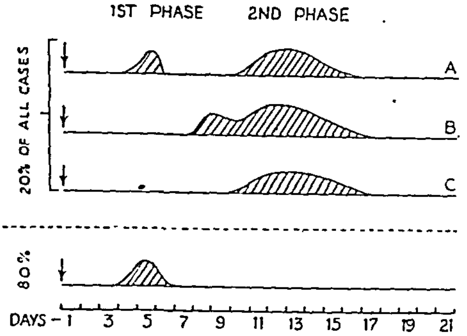

Fig. 1.—The common clinical forms of poliomyelitis (modified from Cecil's Textbook of Medicine, 1947). Shaded areas indicate periods of fever. Arrows on the left mark the hypothetic time of exposure. The abortive form is estimated as representing 80 per cent of all cases, those with central nervous system signs 20 per cent. *A* represents the "dromedary" form; and *B* and *C*, other variations described in the text.

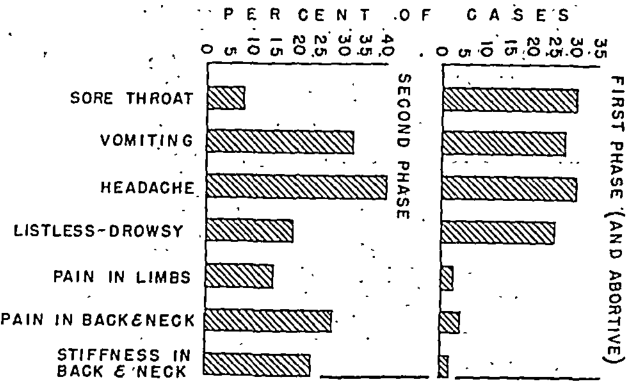

Fig. 2.—Frequency of various symptoms in poliomyelitis during the first and early second phases of the "dromedary course" and in the mild abortive form. (These figures were taken[8] from a study of 195 cases of poliomyelitis by Paul, Salinger and Trask.)

In a patient with a diphasic course such as has been described there is a possibility of at least two interpretations as far as the first day of disease is concerned. It has been our practice to consider the incubation period as the interval between exposure and the appearance of first phase symptoms, regardless of the clinical form which the disease may assume and even if the first phase symptoms are slight. This is not a general practice, for some clinicians consider the incubation period to be the time between exposure and the second phase, i. e. the onset of clinical signs of involvement of the central nervous system. That the results obtained differ by one to four or more days, depending on which of these measurements is used, has been mentioned by workers in this laboratory[9] and by Casey.[4]

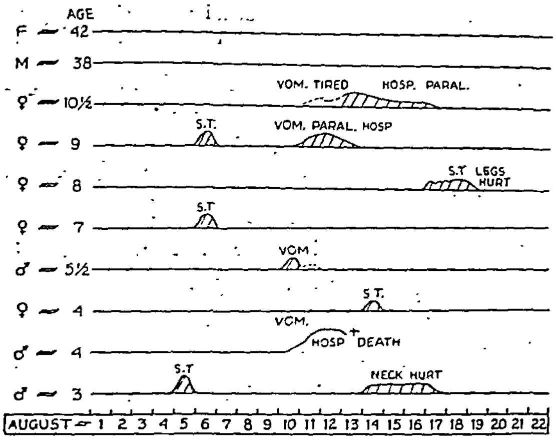

Fig. 3.—A family outbreak of poliomyelitis. Shaded areas indicate periods of fever. S. T., sore throat; Vom., vomiting; Paral., paralysis, and Hosp., hospitalized.

Other clinical forms of poliomyelitis, labeled *B* and *C* in figure 1, illustrate cases in which first and second phases of the disease are partially superimposed, or the first phase is missed or does not occur. In these instances the incubation period by clinical standards necessarily becomes the interval between exposure and the appearance of the phase of illness associated with signs of involvement of the central nervous system.

Family outbreaks of poliomyelitis present opportunities for study of these various clinical patterns. A family manifesting several of the common clinical forms of the disease was studied recently by a member of the Yale Poliomyelitis Study Unit. This family consisted of a mother and father and eight children, and among these eight children presumably 8 cases of poliomyelitis occurred (fig. 3). Since no virus studies were attempted none of the abortive cases can be considered proved, but circumstances strongly suggest that the illnesses were all poliomyelitis. One child, aged 9 years, had a typical dromedary course with the first phase August 6, followed by the second phase four days later, ending with paralysis. Two other children, aged 7 years and 3 years, had first phase symptoms more or less simultaneously, but the child of 7 recovered completely with no recurrence of symptoms, whereas the child of 3 had stiff neck and fever after a long interval of ten days. Second phase symptoms probably began about the same time in 3 children, aged 10½, 9 and 4 years. Two of these had experienced no first phase symptoms. In the child aged 4 years, one of twins, there rapidly developed bulbar signs, and death ensued. In addition 2 other children, aged 8 years and 4 years (the second twin), had minor symptoms several days later than did the rest of the family.

What were the incubation periods in these various cases? Many features suggest a common time of exposure. These are the compactness of the outbreak and the fact that both of the children having "dromedary" courses had first and second phases at about the same time while in the 2 paralytic cases without prodromal phases the patients exhibited their paralytic signs at the same time as did the 2 with dromedary courses. It is possible, nevertheless, although much less likely, that several of the cases could be secondary ones. The history of this family, with its variety of types of onset, illustrates the difficulties which are inherent in the problem of estimating the incubation period on the basis of clinical data.

The complexities are further brought out by the observations of Brown, Francis and Pearson [7] mentioned previously. These authors isolated virus from the stools of a boy nineteen days before paralytic poliomyelitis developed! This observation also raises other questions, namely, what does the incubation period mean in terms of the pathogenesis of poliomyelitis, and what pathogenic processes are reflected in the various clinical forms outlined above (fig. 1 *A*, *B* and *C*)? Draper [10] interpreted the latter problem more than twenty years ago by designating the first phase of the dromedary form, as the period of "systemic reaction to generalized infection; the second a highly specialized reaction of the meninges, brain and cord . . ." According to this interpretation the incubation period would be the time between exposure and the beginning of the systemic reaction, a view which is only partially in keeping with our own present interpretation. Thus the incubation period might be regarded as the interval between the introduction of virus into the body and the appearance of clinical symptoms resulting from its implantation in a number of tissues of the host. These tissues include not only the pharynx and the intestinal tract but the central nervous system and perhaps other anatomic sites. They have been illustrated schematically in figure 4, in which the diagram indicates possible courses of events. Whether the virus enters by way of the mouth (or nose) and goes thence to the pharynx, it probably appears within the upper and/or lower portion of the gastrointestinal tract within seventy-two hours.[11]

Furthermore, it seems that implantation in the wall of the pharynx and intestinal tract occurs soon after the introduction of virus into the body. In these sites it probably multiplies—or it may multiply elsewhere—and is excreted with the feces. But whether or not these activities are always accompanied by concurrent invasion of the central nervous system is not known.

The way in which paralytic poliomyelitis follows within a few days to several weeks after tonsillectomy in a person who presumably already harbors the agent in his throat makes it seem possible that virus can remain localized in the throat and spread to the central nervous system when the host-virus equilibrium is upset by local peripheral trauma. In the case of tonsillectomy the time interval between the exposure of cut nerve endings at operation and signs of disease of the central nervous system is compatible with spread of virus via the nerves to the medulla. Nevertheless another explanation is possible, in that local peripheral trauma may be reflected in the corresponding areas of the cord in the form of central changes which favor activation of virus already present in the central nervous system.

Fig. 4.—The pathogenesis of human poliomyelitis—a possible course of events when virus is introduced into the body for the first time. Blackened areas indicate the localization of virus in anatomic sites (based on clinical and autopsy studies). Dotted areas indicate sites where the virus *may* be located. The middle panel represents the situation in a mild abortive attack and in the first phase symptoms of a dromedary case. The panel on the right represents the frank case. Presumably the processes represented in these diagrams may be arrested at any one of the three stages depicted. I.N., intranasal; I.C., intracutaneous. Dr. R. Ward assisted in the preparation of this diagram.

Studies in the experimental disease provide evidence on this question. Bodian and Howe [12] have demonstrated the presence of lesions in the central nervous system of orally infected chimpanzees who had inapparent or abortive poliomyelitis. If one can draw analogies from the experimental disease, this finding may indicate that early invasion of the central nervous system is common, so that by the time virus is present in the stools it may be presumed to be present in the central nervous system as well.[12] If such is the case, it is conceivable that the first phase of the dromedary type of the human disease or the abortive illness is frequently associated with some invasion of the central nervous system. The observation made by Andelman, Fishbein, Casey and Bundesen [13] on the elevation of the protein level of the cerebrospinal fluid several weeks after the acute infection in abortive poliomyelitis strengthens this supposition, but it remains to be proved. The history of rapid—almost immediate—onset of paralytic poliomyelitis in man following severe exercise is a phenomenon which also suggests that in persons so affected the virus is already present in the central nervous system; exercise is the factor which produces physiologic changes capable of upsetting the host-virus equilibrium, thus allowing virus to spread widely within the central nervous system and cause damage sufficient to produce clinical signs of disease.

[10] Draper, G.: Acute Poliomyelitis, in Nelson's Loose-Leaf Living Medicine, New York, Thos. Nelson & Sons, 1926, chap. 31, pp. 67-84.

[11] (*a*) Evidence for this is based on the fact that poliomyelitis virus fed to chimpanzees has been recovered readily from their stools one to two days later (Melnick, J. L., and Horstmann, D. M.: Active Immunity to Poliomyelitis in Chimpanzees Following Subclinical Infection, J. Exper. Med. **85**: 287-303 [March] 1947). (*b*) Virus has been introduced into the skin of monkeys and chimpanzees and found in their stools as soon as three days after inoculation—several days before clinical signs of disease appeared (Melnick, J. L.: The Recovery of Poliomyelitis Virus from the Stools of Experimentally Infected Monkeys and Chimpanzees, J. Immunol. **53**: 277-290 [July] 1946).

[12] Bodian, D., and Howe, H. A.: Non-Paralytic Poliomyelitis in the Chimpanzee, J. Exper. Med. **81**: 255-27) 1945.

In experimental poliomyelitis variation in the incubation period is common, depending to some extent on the animal species, the dose, the route of inoculation and the strain of virus used. Rhesus monkeys, when inoculated intracerebrally with recently isolated human strains, usually manifest fever and paralysis between six and fourteen days after inoculation. If the monkey-adapted MV strain is employed the incubation period is shorter—three to six days. The same difference between the two types of strains was noted by Howe and Bodian [14] when rhesus monkeys were inoculated by way of the peripheral nerves, the fresh strains producing paralysis in eight to thirteen days and the MV strain in four to five days. Howe and Bodian, by the administration of virus-containing human stools orally and by stomach tube produced paralytic poliomyelitis in 2 chimpanzees after incubation periods of twelve and twenty-eight days, respectively.[14] An infant rhesus monkey has been infected by the oral route nineteen days after its first and six days after its last exposure to virus.[15] The extremes reported have ranged from two days when virus-containing human stool suspensions were introduced directly into the lumbar cord of rhesus monkeys [16] to seventy-one days in a monkey inoculated intracerebrally.[16]

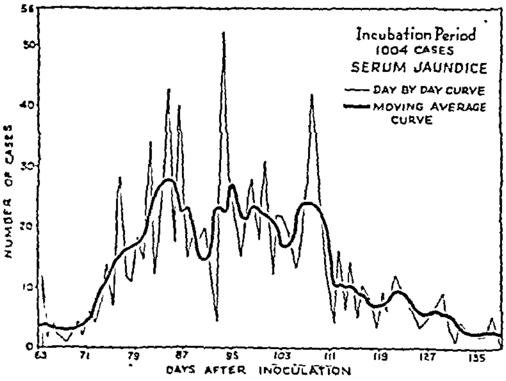

Fig. 5.—The variation in incubation period of homologous serum hepatitis in 1,004 persons inoculated with the same dose of the same lot of the same material on the same day (from Parr [19]).

In another host, namely mice, irregularities are still greater. Using the Lansing rodent-adapted strain and inoculating the animals intracerebrally, the incubation period is usually between two and ten days, but occasionally it has been noted to be as short as twenty-four hours and as long as ninety-three days.[17] With the rodent adapted Y-SK strain it varies between two and eighty-two days in our laboratory. Although the majority of animals become paralyzed three to six days after inoculation, a significant number become paralyzed as late as forty to fifty days. At times there is a grouping of illnesses about certain days, resulting in a diphasic curve which resembles that seen in epidemic diseases showing primary and secondary waves of cases. Similar observations have been made with the Lansing strain in mice.[18]

These results with the experimental disease indicate wide variations in the response of individual hosts to an infectious agent introduced under the same conditions, and there is reason to believe that in the human host similar variations occur. This variability of response is not often subject to measurement in the human host in any disease, but the occurrence of homologous serum hepatitis in members of the armed forces provided such an opportunity. Parr [19] has described an outbreak which occurred at Camp Polk in 1942. On February 27, over 5,000 soldiers were inoculated with a yellow fever vaccine containing human serum. As the result of an icterogenic agent in the vaccine 1,004 cases of homologous serum hepatitis developed among the soldiers, all of whom had been injected on the same day with the same dose of the same lot of material. Figure 5, taken from Parr, illustrates the incubation period in these cases. It ranged from sixty-three to one hundred and thirty-seven days, and the curve is not unlike those which may be drawn by plotting the onset of cases in a number of epidemics of differing types. Although homologous serum hepatitis is a disease which differs from poliomyelitis in that it characteristically has an extremely long incubation period, these figures nevertheless bring out a factor common to all infectious disease, namely, the role of variation in the response of a host to an infectious agent. There is evidence to suggest that this might be an important factor in human poliomyelitis.

COMMENT AND SUMMARY

While analogies may be drawn between the observed incubation period in experimental poliomyelitis and that estimated for the human disease, exact information concerning the latter cannot be obtained in this fashion. It should be emphasized, however, that poliomyelitis virus is capable of great variability in behavior in various hosts under different conditions; in the human disease the interval between apparent exposure and the onset of clinical symptoms and signs has been observed to be as short as three and as long as thirty-five days, with many cases developing after a four to ten day period. But unsolved problems as to what constitutes exposure, what role latency may play and what the pattern of pathogenesis is, represent some of the factors to be elucidated before exact knowledge of the incubation period in human poliomyelitis can emerge.

THE EMERGENCY TREATMENT OF VASCULAR OCCLUSIONS

EDGAR V. ALLEN, M.D.
Rochester, Minn.

This discussion will be limited to consideration of sudden peripheral arterial occlusion (embolism and thrombosis), to acute venous thrombosis and to embolism of the pulmonary arteries. The substance of this paper is the result of the observations of my associates Drs. N. W. Barker, E. A. Hines Jr. and Walter F. Kvale, as well as of my own observations. I may remark, parenthetically, that the use of anticoagulant agents in acute myocardial infarction is now well established, although final evaluation of their use must await further experience, such as that being acquired by workers under the supervision of the American Heart Association. It is safe to conclude now that the anticoagulant agents heparin and dicumarol may be used with safety in acute myocardial infarction. The five clinical reports available indicate, in the aggregate, that the use of anticoagulant agents lessens the percentage of deaths from acute myocardial infarction and sharply diminishes the incidence of arterial embolism, venous thrombosis and additional myocardial infarction after acute myocardial infarction.[1] It is a method of treatment which has gained increasing favor in the past two years.

There has been little new in the treatment of acute arterial occlusion (thrombosis and embolism) of the cerebral circulation. This is a field for study in the future. Perhaps intensive consideration of this problem will be as productive, at least in part, as has that of the acute vascular occlusions to be considered in this presentation.

THE USE OF HEPARIN AND DICUMAROL

Because administration of the anticoagulant agents heparin and dicumarol is an integral and important part of the treatment of the acute venous and arterial occlusion to be considered subsequently, it is well, first, to have a clear understanding of the use of them. Both are used for the purpose of halting intravascular thrombosis. The use of heparin is advantageous in that it has a quick effect on coagulability of the blood, in that its effect quickly ceases when administration is discontinued and in that the drug can be administered without laboratory control. It has the disadvantages of being expensive (about $9 a day) and of requiring parenteral administration. It can be administered effectively by repeated single intravenous injections of 50 mg. every four hours. A combination of heparin with gelatin, dextrose and glacial acetic acid (Pitkin menstruum) may be injected subcutaneously; the heparin is then absorbed slowly, so that injection carried out every two or three days may have sufficient anticoagulant effect.[2] Heparin should be used whenever a quick effect is desired and whenever the absence of wholly reliable laboratory facilities for determination of values for prothrombin in the blood make the use of dicumarol inadvisable.

The administration of dicumarol is advantageous in that the drug is effective when administered orally and in that it is cheap (a few cents a day). It is disadvantageous in that its effect on prothrombin in the blood is delayed (twenty-four hours or longer), that its effect continues after discontinuation of administration (two days or longer) and that entirely reliable laboratory facilities are necessary for safe and efficient administration.

The danger of hemorrhage attends the use of both heparin and dicumarol, but this danger is minimal when they are used judiciously and expertly. If bleeding occurs during the use of dicumarol or if excessive deficiency of prothrombin results, the intravenous injection of vitamin K will restore the prothrombin in the blood to normal or nearly normal values. The transfusion of fresh blood is advisable if bleeding is excessive. My associates Drs. T. W. Parkin and W. F. Kvale have demonstrated the effectiveness of protamine in neutralization of the effect of heparin. Fifty mg. of protamine injected intravenously will neutralize the effect on the blood of 50 mg. of heparin. The methods of use of heparin and dicumarol are presented in table 1. The danger of hemorrhage, the conditions in which anticoagulant agents are to be used cautiously or avoided and the method of calculation of the percentage of prothrombin from prothrombin "time" have been discussed in detail in other presentations.[3]

Table 1.—*Methods of Use of Anticoagulant Agents in Acute Vascular Occlusion*

I. Emergency or use in absence of laboratory facilities for determination of prothrombin in the blood
    a. 50 mg. of undiluted heparin, injected intravenously every four hours
II. Absence of emergency: adequate laboratory facilities available
    a. 300 mg. of dicumarol on first day
    b. 200 mg.* on each subsequent day that value for prothrombin in the blood is greater than 20 per cent
III. Emergency and continued use of anticoagulant agents
    a. 50 mg. of heparin every four hours and dicumarol as indicated in II, above
    b. Heparin discontinued when the value for prothrombin is 30 per cent or less
    c. Blood for determination of prothrombin should be obtained not less than three hours after last injection of heparin, since presence of heparin in the blood gives a value for prothrombin which is falsely small

* In instances in which the drug produces excessive effects on the concentration of prothrombin in the blood, 100 mg. may be used instead of 200 mg. Infrequently, more than 200 mg. may be needed. The aim of treatment is to maintain the values for prothrombin between 10 and 30 per cent.

VENOUS THROMBOSIS

The chief danger of venous thrombosis in the extremities is pulmonary embolism. Venous thrombosis, however, may produce venous obstruction and,

at a remote time, the manifestations of chronic venous insufficiency of the lower extremities, easily recognized as edema, varices, stasis dermatitis and cellulitis, and stasis ulceration of the skin. When the physician sees a patient who has venous thrombosis in the legs, his chief concern is prevention of fatal pulmonary embolism. Anticoagulant agents are effective in this regard in most instances (table 2). The secondary concern is halting the process of venous thrombosis. Anticoagulant agents likewise are effective in this regard (table 2). The anticoagulants may be used in the postpartum state without unusual danger from uterine bleeding.[4]

In addition to the use of anticoagulants, I recommend elevation of the involved extremity and the application of a moist warm pack.

It may be advisable to use the program outlined in the third section of table 1 in all cases of venous thrombosis. Actually, clinical experience has indicated that dicumarol alone is effective in most cases. If the venous thrombosis is extensive or if it is progressing, both heparin and dicumarol should be used. Dicumarol should be used until there has been no evidence of new venous thrombosis for seven to ten days. The patient may be active when dicumarol has produced satisfactory reduction of prothrombin in the blood. If there is edema at this time, an adequate support must be worn until it can be discarded without permitting edema.

Table 2.—*Results of Anticoagulant Therapy in 352 Cases of Postoperative Venous Thrombosis*

Condition to Be Prevented	Cases: Expected if Anticoagulants Had Not Been Used	Cases: Actual Number
Subsequent venous thrombosis or pulmonary embolism	88	9*
Subsequent fatal pulmonary embolism	20	0

*One case of minor pulmonary infarction and 7 cases of venous thrombosis; in 3 cases the percentage of prothrombin in the blood was more than 30. In 1 case treatment with dicumarol had been discontinued and prothrombin was normal.

It is my belief that the use of anticoagulant agents is, in general, superior to ligation of veins as a therapeutic procedure in acute venous thrombosis, although in many instances[5] there is no doubt of the effectiveness of ligation of veins. It appears to me that, with three exceptions, the record for the use of anticoagulant agents is better than that of ligation of veins. Ligation of veins is superior in the prevention of pulmonary embolism arising from thrombi in the veins of the legs which recur repeatedly at long intervals, because it is difficult to use anticoagulant agents for long periods. Ligation of veins is the treatment of choice when anticoagulants are contraindicated and when they are ineffective, as is very rarely the case.

We have had some experience with injection of a local anesthetic agent into the paravertebral sympathetic ganglions when acute venous thrombosis occurs. This procedure does not prevent pulmonary embolism or halt venous thrombosis. I know of no acceptable evidence that it lessens the remote effects of venous thrombosis; that is, chronic venous insufficiency, which produces varices, dermatitis and ulceration. It lacks effectiveness, therefore, in prevention of the three major complications of venous thrombosis. I do not deny that this method may lessen the pain of venous thrombosis, but such pain usually is minimal and unimportant, responding satisfactorily to the oral administration of anodynes. Anesthetization may lessen fever, but fever is transient, is minimal to moderate and is not important. The procedure may hasten the disappearance of edema, but this ordinarily is accomplished by simple elevation of the limb. Anesthetization of appropriate paravertebral ganglions may lessen the arterial spasm occasionally associated with venous thrombosis, but the local application of a warm pack may be as effective. Hence, the injection of anesthetic agents certainly has limited usefulness, and my experience, as well as that of some of my experienced surgical colleagues, has led to sharp restriction of the use of anesthetization of paravertebral ganglions in the treatment of acute venous thrombosis.

Table 3.—*Treatment of Acute Peripheral Arterial Occlusion (Embolism and Thrombosis)*

I. Early diagnosis and treatment
II. Relieve pain
    a. Opiates as needed
III. Avoid measures which do harm, such as
    a. Application of heat
    b. Elevation of the extremity
IV. Administer anticoagulant agents
    a. Heparin and dicumarol
V. Relieve arterial spasm
    a. Heat
        1. Warm environment; room temperature about 90 F.
        2. Apply warm packs to other than involved extremities
    b. Alcohol by mouth (liberally !); Papaverine (see table 4)
    c. Anesthetization of appropriate sympathetic nerves
        1. Spinal or caudal anesthesia
        2. Paravertebral anesthetization of sympathetic nerves
    d. Oscillating bed if available
VI. Embolectomy, provided medical treatment is not effective in greatly improving the circulation within 6-12 hours and provided hopelessness of saving the limb is not already apparent

Table 4.—*Treatment of Pulmonary Embolism*

I. Emergency treatment
    a. 1/60 grain atropine sulfate and ½ grain of papaverine hydrochloride intravenously
    b. Oxygen by inhalation
    c. 50 mg. of heparin intravenously and 300 mg. of dicumarol orally
    d. Avoid use of morphine, epinephrine and digitalis
II. Continued treatment
    a. Repeat injections of atropine and papaverine every 4 to 6 hours as needed
    b. Oxygen as needed
    c. Heparin and dicumarol
III. Absence of emergency
    a. Heparin and dicumarol

SUDDEN ARTERIAL OCCLUSION IN THE EXTREMITIES

It is well to bear in mind the fact that arterial embolism ordinarily produces much more profound effect on the arterial circulation than does simple interruption in the continuity of a major artery.[6] The ischemia which results is caused in a large part by the spasm of collateral arteries induced by the presence of an embolus. If such ischemia persists for more than a few hours, the intima of blood vessels distally is injured to such a degree that intravascular thrombosis occurs when blood again runs into them. The ischemia which originally was caused by mechanical obstruction of an artery by an embolus and by arterial spasm eventually is the result of arterial thrombosis if treatment is delayed or inadequate. These events appear less striking in acute arterial thrombosis but are nonetheless important. The treatment of acute peripheral arterial embolism is outlined in table 3. Better understanding of the abnormal physiology involved in arterial embolism and the use of methods to correct it have resulted in far better results than were obtained a few years ago At the Mayo Clinic we have treated 19 patients who had acute arterial embolism with most of the methods outlined in table 3, excepting spinal and caudal anesthesia and embolectomy. Some of the cases concerned have been reported previously.[7] Treatment was begun early in 11 instances; there was recovery of the circulation to the limb in 10 instances. In 8 instances treatment was begun more than twenty-four hours after embolism had been sustained. Recovery of circulation occurred in only 2 cases. In 16 instances treatment was initiated within twenty-four hours of the onset of acute arterial thrombosis; recovery occurred in 13 instances. In 10 instances treatment was begun twenty-four hours or more after the onset of acute arterial thrombosis; recovery of the limb concerned occurred in 5 instances.

Table 5.—*Results: 329 Cases of Pulmonary Embolism in Which Anticoagulant Therapy Was Used*

Condition to Be Prevented	Cases	
	Expected If Anticoagulants Had Not Been Used	Actual Number
Subsequent venous thrombosis or pulmonary embolism	144	3
Subsequent fatal pulmonary embolism	60	1*

* Occurred after prothrombin time had returned to normal.

These figures emphasize adequately that the early institution of measures to diminish the coagulability of the blood and to relieve arterial spasm, along with avoidance of harmful measures, has greatly brightened the outlook for recovery of limbs affected with acute arterial occlusion. The figures emphasize also the predominant role of medical treatment and the greatly reduced need for surgical treatment of acute arterial embolism.

PULMONARY EMBOLISM

Knowledge of the mechanisms which are initiated by pulmonary embolism has progressed rapidly in recent years. Death from pulmonary embolism is not solely the result of mechanical plugging of a pulmonary artery. When an embolus lodges in a pulmonary artery, arterial spasm, bronchospasm, atelectasis, deposition of a thrombus on the embolus and coronary insufficiency occur. These are the agents of death in pulmonary embolism. We are much indebted to de Takats and Katz and their respective associates for these observations.[8]

The treatment of pulmonary embolism is outlined in table 4. Every hospital should be prepared for the emergency treatment of pulmonary embolism. Although no final conclusion has been reached concerning the effectiveness of emergency treatment, it is probable that it can save many lives.

When a patient has recovered from pulmonary embolism, the major problem is the prevention of a second episode, which in many instances will be fatal. Experience has indicated clearly that pulmonary embolism from which a patient has recovered frequently is only the pilot event of a more catastrophic—indeed, a lethal —process of embolism.

The experience at the Mayo Clinic indicates clearly the effectiveness of the anticoagulant agents in the prevention of additional pulmonary embolism, once pulmonary embolism has occurred.[9] The most recent evaluation of the use of such agents postoperatively is presented in table 5. The remarks made previously concerning the comparative usefulness of ligation of veins are pertinent in this consideration.

SUMMARY

In recent years the management of patients who have acute vascular occlusion has become eminently more satisfactory. Understanding of the mechanisms involved, achieved by experimental and clinical observation and early and adequate treatment, has greatly improved the outlook for patients who have acute intravascular thrombosis. Many lives and limbs can be saved and many patients can be spared the distressing experience of pulmonary embolism and chronic venous insufficiency, which is the remote result of extensive venous thrombosis, if treatment based on wisdom and understanding is instituted early.

Virchow and a New Epoch.—In 1858 a young man of 37 gave a series of lectures in Berlin to a group of medical men. These lectures, later published under the title Die Cellularpathologie, ushered in a new epoch. The young man was Rudolf Virchow. He has been acclaimed, perhaps a little extravagantly, as the greatest figure in medicine since Hippocrates. By applying the cell theory of Schleiden and Schwann to pathology he transferred medicine from its ancient foundation on the four humors of the Greeks to a new foundation, the fundamental unit of modern biology, the cell, and transformed pathology itself into a modern science. At the same time, in the same book, he established the dictum *omnis cellula e cellula,* which has proved to be one of the most important axioms of biology. In these lectures we find epitomized the interaction between medicine and biology, which has repeatedly contributed to the advancement of both.—Wilson, J. Walter: Virchow's Contribution to the Cell Theory, *Journal of the History of Medicine and Allied Sciences*, Spring 1947.

SUPPORT OF THE PARALYZED FACE BY FASCIA

JAMES BARRETT BROWN, M.D.
and
FRANK McDOWELL, M.D.
St. Louis

In paralysis of the facial nerve, the temporal muscle and its fascia can be used for supporting the drooped tissues of the face. For this the muscle is connected to the face by loops of fascia lata, and it can then straighten the deviated mouth and columella nasi and support them in the normal position. The nasolabial fold is often reformed, and a small amount of movement may be produced by the muscle which is controlled by the fifth cranial nerve. Patients are grateful also for the improved control of the mouth, which permits them to smoke, whistle and eat and drink in public.

The procedure does not disturb the patient much, does not impair the functions of other nerves or leave visible facial scars. Five or six days' hospitalization is recommended, with an additional week of outpatient care. Worth while improvement is usually noted at once.

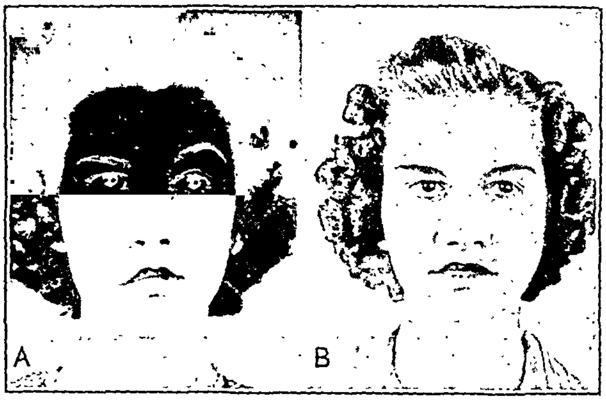

Fig. 1.—*A*, total paralysis resulting from removal of malignant parotid tumor (elsewhere). All of the branches were individually severed in the parotid area. *B*, after one operation the patient appears quite normal in repose and with small smile. She attends a university and does well.

INDICATIONS FOR OPERATIVE REPAIR

The operative intervention is indicated when the paralysis of the facial nerve seems to be permanent and when direct suturing, nerve grafts or anastomoses are not feasible—or when these have been tried and have not produced the desired result. It may also be used primarily in conjunction with any of the nerve operations.

THE OPERATIVE PROCEDURE

Endotracheal anesthesia of the patient is employed with the tube coming out the opposite corner of the mouth. Strips of fascia lata 4 to 8 mm. wide are obtained in the longest lengths possible from the iliotibial band, by use of the Masson or other stripper. The temporal incision is made in the hair-bearing area and is carried down to the temporalis fascia. A small stab opening is made in the middle of the upper lip and another one in the lower lip 1 to 2 cm. outside the angle of the mouth and 1 cm. below the vermilion. The first strip is then passed subcutaneously from the temporal wound down through the face, out of the stab opening in the upper lip and back up to the temple by a different route, so that it forms a loop and encircles a good deal of soft tissue in the lip. Another strip is passed similarly down to the stab opening in the lower lip and back, care being taken again to avoid puncturing the buccal mucosa. The fascia may be carried through the face by a Blair fascia needle or by an ordinary long sack-sewing needle.

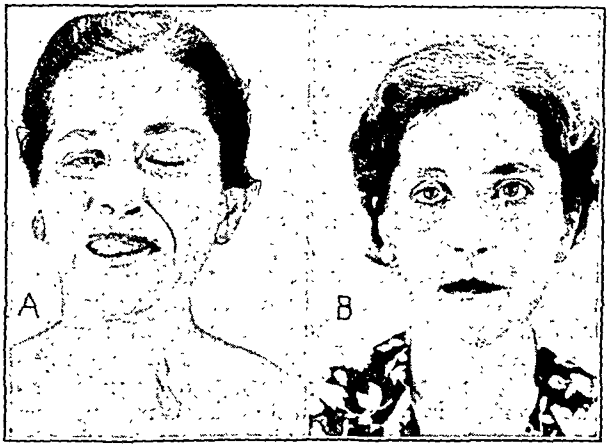

Fig. 2.—*A*, paralysis which resulted from the removal of an intracranial tumor and was repaired by anastomosis of the eleventh nerve (elsewhere). In this instance the patient recovered only mass movements, the muscles working on an "all or none" basis and not very helpful in expression. *B*, after fascial transplant the patient has learned not to use the anastomosis and has even requested that it be disconnected.

After being placed, the loops are worked back and forth a little to take out any slack and the temporalis fascia is opened about 1 inch (2.5 cm.) above the coronoid to expose the muscle fibers. A heavy full curved fascia needle is used, and one end of each strip is passed around a substantial segment of muscle and tied to the other end by a surgeon's knot. The knots are pulled taut with the mouth in considerable overcorrection and then fixed by taking several interrupted silk stitches through the knots and by sewing the ends of the strips down. A pressure dressing is applied to cover the eye, ear and entire side of the face; this helps materially in getting smooth early healing.

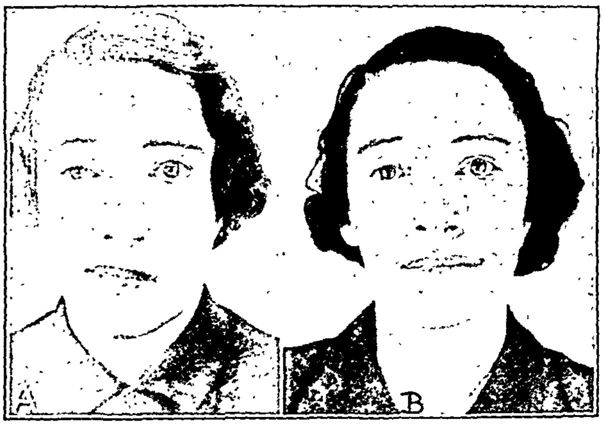

Fig. 3.—Result (*A*) following free nerve graft (elsewhere) for paralysis; *B*, after fascial transplant. Figures 2 and 3 are shown not as an argument against the nerve operations but to note that something further can be done when they do not work as well as expected.

From the Department of Surgery, Washington University School of Medicine.

POSTOPERATIVE CARE

The pressure dressing is left on four or five days (if the eye is comfortable) and then replaced by a smaller one. Chewing is limited for the first week but is gradually resumed as any tenderness in the temple subsides. The overcorrection disappears within about ten days, and after two or three weeks the patient may practice biting down in front of a mirror until he can produce some lateral movement of the mouth. He notes how this is done and then strives to increase the extent of the movement. A little later he may try to balance the movement with a small smile on the normal side; meanwhile he should practice repressing the movements on the normal side. This latter point is emphasized, as almost any patient with a facial paralysis will try so hard to move the paralyzed side that he will form the habit of exaggerating the movements of the normal side. He must learn that balance in the face is more important than the actual range of motion and must always strive for this balance. As a starting point, he may consciously try to remain a little glum and then work from this point forward as he learns better control of his expressions. Sudden large laughs can never be adequately balanced in these patients and may reveal a paralysis which is otherwise fairly well controlled.

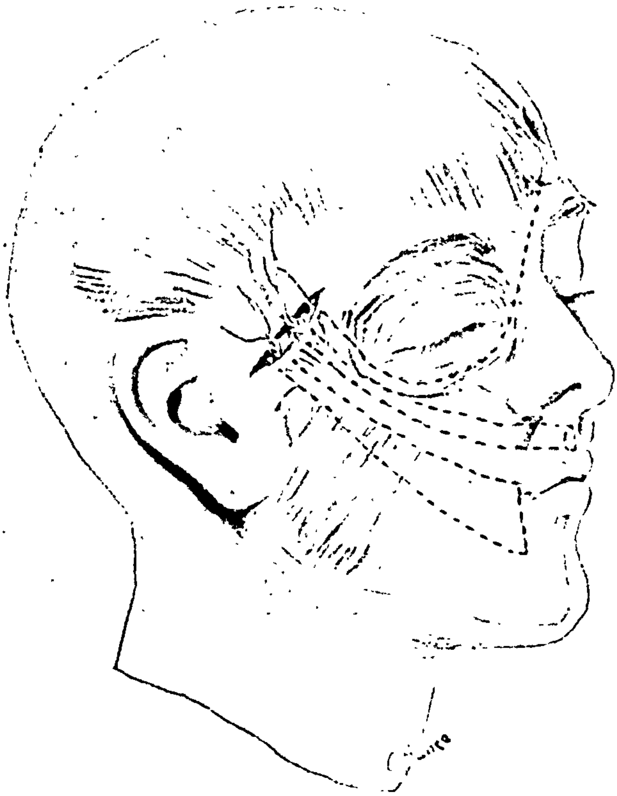

Fig. 4.—Diagram showing the location of the two main fascial loops in the face. An additional strip is sometimes placed in the lower eyelid and anchored to the temporal fascia on the same side and to the frontalis muscle on the opposite side when it is impossible to correct the lagophthalmos by a canthoplasty or other local operation on the eyelid.

VARIATIONS IN THE OPERATION

Preserved fascia, Kangaroo tendon and wire have been used, but it is thought that autogenous fascia is superior to any foreign material, and it is easy to obtain.

Additional loops may be put in to the prominence of the cheek, around the mouth or to the angle, but the two simple slings which have been described usually suffice.

The anchorage above may be to the temporal fascia or to the zygomatic arch rather than to the muscle, but this does not permit any movement of the face or even enough to take any slack out of the loops if they stretch or slip a little.

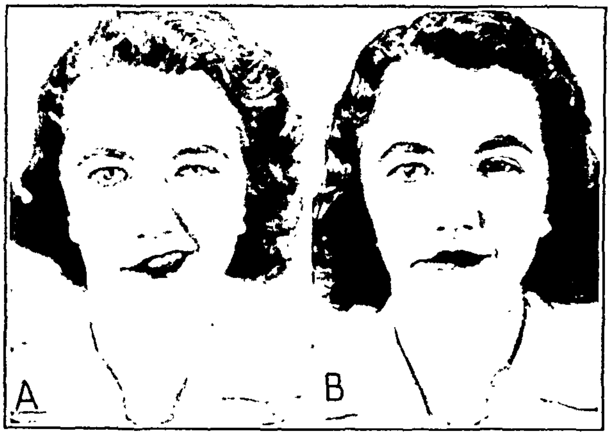

Fig. 5.—*A*, congenital paralysis of twenty years' duration. *B*, the result of a single operation (fascial transplant). The patient has a good personality and nice features and has since married. (The difference in the palpebral features is made more noticeable by the squinting of the normal lids because of the strong lights used to take this photograph.)

Older persons with paralysis of long duration may have considerable excess skin. This may be excised by a unilateral face-lifting operation as a separate procedure. It is a little safer to do it before the fascial transplant, but the amount to be excised can be estimated better afterward. Younger patients, or those with paralysis of lesser duration, will usually tighten up the stretched skin spontaneously during the first few postoperative months.

THE EYELIDS AND FOREHEAD

The paralyzed upper lid seldom requires any treatment (unless combined with paralysis of the third nerve) but the sagging lower lid may create a larger palpebral fissure, apparent or actual exophthalmos and a staring expression. The general elevation of the face usually helps this, and nothing else is required in some cases. If this is not sufficient, a small external canthoplasty may be performed, excising a full thickness wedge of the lower lid near the outer canthus. Occasionally it is worth while to put a thin fascial strip horizontally through the lower lid near the tarsal

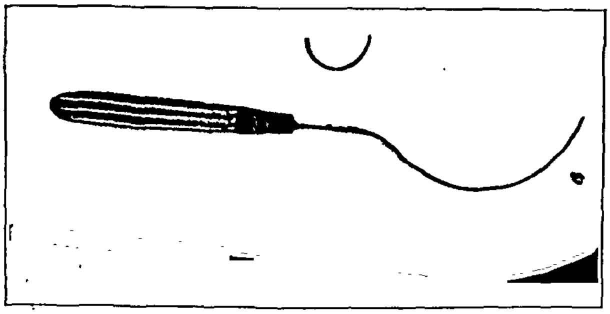

Fig. 6.—Three needles ordinarily used for placing the fascial strips, from above downward: Gallie needle used for anchoring the strips in the temporal muscle; semicircular needle used for placing strip in lower lid, and needle used for placing the main strips in the face. The two lower needles were devised by Dr. Douglas Sanders and are made of bent heavy Kirschner wires with a slot cut in the tip and a handle mounted on the end.

border, anchoring it externally to the temporal fascia above and medially to the opposite frontalis muscle or fascia. These operative corrections do much to prevent irritation to the globe, but it is always advisable for the patients to avoid excessive exposure to strong, cold winds or to dust.

No known operative procedure will restore movement to the forehead. However, if the brow is heavy and low it may be elevated by excising an ellipse of skin in the hair line just above, undermining and sliding that side of the forehead up. A separate strip of fascia may be put in from high in the temporal region, through the brow and then carried high up on the opposite side and anchored.

The amount of movement obtained varies from little to a noticeable amount, the majority of persons obtaining a small range of definitive motion which is of value in expression. The cause of this variation is not entirely understood, though some persons seem to have much thicker and more active muscles than others. An occasional patient will have the fascial loops "freeze" to all the surrounding tissues throughout their length; this almost precludes movement but leaves the face balanced in repose, which is still worth while. The patient's own efforts and general morale have considerable influence on the final result in many cases.

The point of initial overcorrection should be mentioned again. We have never had to loosen any of these loops secondarily (even when the mouth was pulled far over to the paralyzed side), though we have had to tighten them in a few instances and to insert additional loops later in a few others. The single operation suffices in nearly all patients, and it is not entirely clear why an occasional loop will need secondary tightening. It may be due to (*a*) stretching of the fascia (or not using wide enough strips); (*b*) the loops cutting through some soft tissue above or below (the reason for encompassing as much soft tissue at either end as possible), or (*c*) persistent overactivity on the normal side.

The most dramatic results are obtained in total paralysis, but worth while results have been obtained in partial paralysis (where nerve operations were contraindicated). In the latter, however, the closer the expression is to normal, the less is to be expected from any operative procedure—since the net gain will be less.

The chief disadvantages of the operation are (*a*) the occasional necessity of secondary adjustments outlined previously and (*b*) the fact that, in common with all other operative measures it does not restore completely normal movements to the permanently paralyzed face.

Among the advantages of the operation may be listed (*a*) its simplicity and directness; (*b*) its early, definite results; (*c*) the absence of resultant annoying tics or mass actions and the minimal possibility of complete failure; (*d*) it can be used later when nerve operations have not been as successful as anticipated or desired; (*e*) it can be used in conjunction with operations on the nerves; (*f*) it can be used in practically all patients, regardless of the cause or duration of the paralysis, and (*g*) it does not produce any additional disability or visible scars.

SUMMARY

Additional observations have been made on the use of the temporal muscle and strips of fascia lata in the treatment of facial paralysis.

DIPHENHYDRAMINE HYDROCHLORIDE ("BENADRYL HYDROCHLORIDE")

Report on Its Use in One Hundred and Thirty-Seven Patients

LESTER S. BLUMENTHAL, M.D.
and
MORRIS H. ROSENBERG, M.D.
Washington, D. C.

Recent investigation has shown diphenhydramine hydrochloride (dimethylaminoethyl benzohydryl ether hydrochloride, "benadryl hydrochloride" N. N. R.) to be an efficient histamine antagonist and an antispasmodic of low toxicity. Loew[1] and his associates demonstrated that fatal bronchoconstriction and symptoms of anaphylactic shock following the inhalation of histamine could be prevented in guinea pigs by prior administration of the drug. Elias and McGavack[2] were able to suppress completely the sensitivity of the skin to histamine, as expressed by the wheal and flare reaction, by the oral use of 150 to 300 mg. of the drug daily in nonallergic persons. Feinberg and Friedlander[3] were able to prevent the appearance of dermographism, which was an obstacle in the performance of skin tests in allergic persons, by giving the antihistaminic agent orally prior to the tests. This did not interfere with the interpretation of the cutaneous tests. The same authors[4] later observed only a slight inhibition on experimentally produced histamine wheals when the drug was given orally. This was in contrast to the definite reduction in the whealing reaction which was observed when the agent was applied locally, whether in combination with or preceding solutions of histamine. They suggested that the action of the drug is by displacement of histamine from its site of action and that failure of oral administration to be effective in certain allergic conditions may result because insufficient quantities of the compound reach the site of action. McElin and Horton[5] stated that the symptoms which occur in allergic disorders as a result of the antigen-antibody reaction in the sensitized cell are due to the release of histamine or a histamine-like substance. Therefore it has been suggested that a histamine antagonist could be used in the treatment of such manifestations.

The present study was undertaken in order to evaluate the use of diphenhydramine hydrochloride in conditions which are generally accepted as being allergic as well as in other states which present similar symptoms but which are not necessarily allergic. A preliminary report has been made on the use of this drug in 41 of the cases herein cited.[6] Since that time 99

RESULTS OF TREATMENT

Urticaria.—Twenty-nine patients with urticaria were treated. Of these, 24 received pronounced relief, 1 obtained moderate relief and 4 were not relieved. Table 2 lists the etiologic agents in cases in which these were known. Thirteen cases were due to sensitivity to drugs, 7 to foods, 1 to wool and 8 to unknown causes. The drugs responsible for sensitivity reactions were penicillin, phenobarbital, sulfathiazole, tetanus antitoxin, potassium thiocyanate, insulin, acetylsalicylic acid and theelin. Allergies to these agents are well known, and the use of "benadryl hydrochloride" in the treatment of such allergies has been previously reported.[7] The foods which produced urticaria in these patients were sea food, tomatoes, fowl and eggs. In addition there were 3 cases of food or drug sensitivity without urticaria which were treated with the compound. One was that of a patient in whom there developed a large wheal at the site of injection of penicillin in oil and beeswax, given ten days previously. This wheal rapidly became larger and was associated with severe localized pruritus. The first dose of diphenhydramine hydrochloride stopped the itching, although the lesion continued to get larger. The patient therefore was maintained on the drug orally for three days, during which time the wheal became progressively smaller and then disappeared. A second patient had a known sensitivity to chocolate, characterized by the appearance of sneezing, burning of the roof of the mouth, coryza and lacrimation after eating chocolate. This patient was relieved of these symptoms by taking diphenhydramine hydrochloride. She also found that if she took a capsule of the drug before eating chocolate the symptoms did not appear. In a third patient severe generalized pruritus without rash developed approximately one hour after each of three injections of morphine. This patient was given a 50 mg. capsule of diphenhydramine hydrochloride after the itching developed, and in twenty minutes he was completely free of symptoms. When he received another capsule prior to the next dose of morphine no reaction occurred. The following day morphine was again administered without a prophylactic dose of the antihistaminic agent, and itching did not occur. Nine of these patients were given intravenous injections of diphenhydramine hydrochloride. The use of the drug intravenously will be discussed later in this article.

Hay Fever.—Twenty-three patients with seasonal hay fever were treated. Of these, 15 received pronounced relief, 5 obtained moderate relief and 3 were not benefited. Many previous reports on the use of "benadryl" in hay fever have been made. Levin [7b] noted that the effect of the drug is generally definite, relief being either decided or not present at all. However, 5 of our patients did receive definite relief which was not complete. The action of the drug may vary at different times. Several patients commented that they were on occasion completely relieved of symptoms and at other times received no relief. It has not been our experience that the patients become tolerant to the drug after taking it for a long period of time or that the drug becomes less efficacious as it is used over that period. One patient who usually discontinues playing golf during the hay fever season was able to play without discomfort by taking a 50 mg. capsule of diphenhydramine hydrochloride prior to playing.

Bronchial Asthma.—Of 12 patients with bronchial asthma treated with diphenhydramine hydrochloride only 1 was decidedly relieved by its use. Three were moderately relieved, and 8 showed no improvement at all. Several authors [8] have reported good results with the use of this drug against bronchial asthma, but most reports indicate that the agent is not particularly effective against this disease. However, we believe that the use of the compound is worth while because an occasional patient is benefited. It was noted that many of the patients who did not respond to the

medicament were made extremely drowsy and were able to sleep. Examination of the chest at that time showed no change in the physical observations. It is considered that the drug acted as a sedative in these cases and that no bronchial relaxation occurred.

Contact Dermatitis.—Sixteen patients with contact dermatitis were treated. Twelve of these received pronounced relief and 4 were moderately improved. The reported effects of the use of diphenhydramine hydrochloride in contact dermatitis vary greatly. Most of the series reported have been small in number. Some investigators have considered [9] that the drug has no place in the treatment of this condition. Others [7b] have reported good results in the relief of the associated pruritus. From the results that we have obtained, we believe that there is a definite indication for the use of the drug in treatment of contact dermatitis.

Functional Dysmenorrhea.—Ten patients with functional dysmenorrhea were treated. Five received decided relief, 2 obtained moderate relief and 3 were not relieved. According to Selle [10] histamine, even in extremely high dilutions, is a powerful stimulant of the uterine musculature. We contemplate undertaking studies to determine whether or not there is an increase in the level of histamine in the blood at the time of menstruation. If this is true, the use of an antihistaminic agent against dysmenorrhea will rest on a sound physiologic basis. The antispasmodic action of the drug and the psychic factor of any type of therapy in dysmenorrhea also must be evaluated in determining the effiicacy of the therapeutic agent. Other reports [11] vary as to the efficacy of diphenhydramine hydrochloride in this condition. There has been no report to our knowledge of results with this drug in a large series of such cases, and until such a report is available no real decision can be reached.

Migraine.—Eleven patients with typical migraine headaches were treated. In 4 the relief was pronounced, in 2 moderate; 5 received no relief. All these patients had previously [12] been relieved by the use of dihydroergotamine.[13] All were told to take 100 mg. of diphenhydramine hydrochloride orally at the first symptom of their migraine attack. In 3 instances this dosage had to be repeated in four hours because the headache returned. McElin and Horton [5] report the use of the drug in 3 cases of migraine without relief. Levin [7b] reported relief in 11 of 18 patients with migraine. He stated that the effect of the drug varied in most of the patients who were relieved and that in several no relief resulted from a dosage which was the same or larger than one which had previously been effective.

Vasomotor Rhinitis.—Three patients with vasomotor rhinitis were treated. One, the patient whose sensitivity to chocolate has been discussed previously, experienced pronounced relief; 1 obtained moderate benefit and 1, no relief.

Spastic Colon.—Diphenhydramine hydrochloride was used in 2 cases of spastic colon with definite relief of symptoms. McGavack, Elias and Boyd [8a] used this agent on 7 patients with spastic colon with excellent relief of symptoms in 3 and improvement in 4.

The same authors [8a] have shown that the compound has a pronounced depressant effect on the presence of both free and total gastric acid in patients who showed free acid prior to the administration of the drug. Moreover, there was little or no response to injections of histamine after the patients had taken the antihistaminic agent orally within one hour before the test. Theoretically the threefold action of the drug, (1) antihistaminic, (2) antispasmodic and (3) sedative, would suggest its use in peptic ulcers and other conditions associated with hyperacidity. Thus far no extensive study of the use of diphenhydramine hydrochloride in peptic ulcers has been reported.

Cardiac Asthma.—Two patients who had persistent cough and mild asthmatic wheezes, which persisted after their congestive cardiac failure was controlled, were given the antihistaminic agent with disappearance of these symptoms. Relief of symptoms in these cases suggests that the compound acted to relieve the bronchospasm that may have accompanied the cardiac failure.

Miscellaneous.—A group of patients with miscellaneous conditions, in all of which there was pruritus, were treated. Three patients with sunburn were definitely relieved of pruritus. Two patients with generalized pruritus without rash were also relieved. Two patients with jaundice and 1 with psoriasis obtained moderate relief. In these it was difficult to determine what role sedation played in the production of relief, because all 3 became extremely sleepy after the administration of one 50 mg. capsule of the drug. Three patients with neurodermatitis were treated, with pronounced relief in 2 and no relief in 1. Treatment of 2 patients with atopic eczema resulted in well defined relief for 1 and moderate relief for the other. One patient with a pruritic rash associated with infectious mononucleosis was decidedly relieved. This case has been previously reported in greater detail.[6] Three patients who had, respectively, dermatitis herpetiformis, pityriasis rosea and senile pruritus were treated without relief. One patient with angioneurotic edema and 1 with Ménière's syndrome were treated with moderate relief. A patient with severe tabetic pains that occurred during the febrile phase of malarial therapy was not relieved by diphenhydramine hydrochloride. Nor was it possible to prevent the pains when the drug was given prophylactically.

Prevention of Transfusion Reaction.—The following case, which has been previously reported,[6] is included here in detail for the purpose of completeness.

Case 1.—E. W., a white man aged 67, was hospitalized in May 1945 for treatment of a bleeding peptic ulcer. During hospitalization he was given five transfusions of compatible whole blood. After each transfusion he had a severe chill, an elevation in temperature to 103 F. and generalized urticaria. In April 1946 operative intervention was performed because of a perforated appendix. During the early part of the patient's stormy course he was transfused twice with compatible whole blood. Each transfusion was followed by a severe chill, temperature of 103 F. and urticaria. When it again became necessary to give a transfusion, the patient was given 50 mg. of diphenhydramine hydrochloride orally twenty minutes before the transfusion was started. The patient had no reaction following the transfusion. Several days later this procedure was repeated with a similar result.

We have since attempted prophylactic treatment with this drug in other patients who have had blood transfusion reactions but required further transfusions. We have treated 4 such patients, in whom the transfusion of whole blood had been followed by reactions consisting of fever (over 101 F.) and shaking chills. In each of the patients a second transfusion of compatible whole blood was preceded by the administration of 50 mg. of diphenhydramine hydrochloride orally; there were no reactions to the transfusions. Another patient received protein hydrolysate intravenously on two successive days, each injection being followed by the appearance of generalized urticaria. On the third day, when 50 mg. of diphenhydramine hydrochloride was given orally prior to the infusion of protein hydrolysate, no urticarial reaction followed the transfusion.

[13] Supplied by Sandoz Chemical Works, New York.

Another patient who had received a large number of transfusions was treated.

Case 2.—L. S., a Negro woman aged 40, was six months pregnant. On admission she had mild diabetes, albuminuria, severe hypoproteinemia and anemia. Her pregnancy was terminated surgically, following which her course was progressively downhill. She died in uremia. Permission for an autopsy was not granted.

Table 3 shows the types of transfusions received by this patient. We have classified the degree of transfusion reaction as follows: Severe: shaking chill, temperature above 101 F., dyspnea, apprehension, nausea, vomiting and tachycardia. Moderate: chilly sensation but no shaking chill, temperature below 101 F. and nausea with or without vomiting during or immediately following the transfusion or within an hour after the transfusion. Slight: slight chilly feeling, no fever, no great interference with the sense of well-being.

From the results obtained we are unable to draw any definite conclusions in regard to the use of diphenhydramine hydrochloride prophylactically in the prevention of transfusion reaction in this patient. It is true that all three of the severe reactions occurred when the drug was not used. In two of the three instances in which a moderate reaction occurred there is a possible explanation because of the interval between the administration of the drug and of the transfusion. Our clinical impression is that the use of the compound prevented this patient from having severe reactions.

Table 3.—*Use of Diphenhydramine Hydrochloride ("Benadryl Hydrochloride") in Prevention of Transfusion Reactions in One Patient*

Case 2	No. of Transfusions	Reaction			
		Severe	Moderate	Slight	None

* Diphenyhydramine hydrochloride given ninety minutes prior to transfusion.

† Diphenhydramine hydrochloride given three hours prior to transfusion.

In 3 patients an attempt was made to prevent recurrent transfusion reactions by the prophylactic use of intravenous injections of the drug. Table 4 shows the results obtained.

Case 3.—D. P., a white man aged 37, had a tendency to bleed since birth (following circumcision; frequent nose bleeds; pronounced bleeding after extraction of a tooth and after an appendectomy). A diagnosis of idiopathic thrombocytopenic purpura was made when he was 24 years of age, at which time a splenectomy was performed. Between the ages of 24 and 28 the patient received twenty-eight blood transfusions. With each transfusion he had a severe shaking chill and elevations in temperature to 102 to 106 F. The chills usually lasted from fifteen minutes to two hours. The reactions were frequently accompanied by backache, urticaria and herpes zoster.

Table 4.—*Intravenous Use of Diphenhydramine Hydrochloride in Prevention of Blood Transfusion Reactions*

Case	Type of Transfusion	No. of Transfusions	Reaction			
			Severe	Moderate	Slight	None

	Without diphenhydramine	5	..	..	..	5

The patient was admitted to this hospital on Oct. 3, 1946 because of bleeding from the gastrointestinal tract. On Oct. 10, 1946 he was given a transfusion of compatible whole blood preceded by 50 mg. of diphenhydramine hydrochloride orally. After receiving 180 cc. of blood the patient had a severe shaking chill; the temperature rose to 101.2 F., the pulse rate was 110, and he was sweating profusely. On Oct. 12, 1946 he was given another transfusion of compatible whole blood without the medicament. After 250 cc. of this transfusion had been given he again experienced a similar severe reaction. That same afternoon he was given the remainder of the blood which had caused a reaction in the morning. This time the transfusion was preceded by the administration of 30 mg. of diphenhydramine hydrochloride intravenously in 100 cc. of isotonic solution of sodium chloride; a reaction did not follow this transfusion.

On Oct. 14, 1946 the patient was given the remainder of the blood to which he had had a reaction on Oct. 10, 1946, and again the transfusion was preceded by the intravenous use of the drug. About thirty-five minutes after the transfusion the patient had a severe reaction characterized by the same manifestations. On Octber 17 and 20 the procedure was repeated, and each time the patient had a severe reaction to the transfusion. Following these experiences the patient was given the red blood cells from 500 cc. of compatible blood, from which the plasma had been removed. Diphenhydramine hydrochloride was not given prophylactically, and a reaction did not occur. This type of transfusion has been repeated on five occasions without subsequent reactions. It is considered that the drug was ineffective in preventing transfusion reactions in this patient.

Case 4.—H. D., a Negro boy aged 13 whose disease was diagnosed as aplastic anemia, received his first transfusion of whole blood without reaction. His second transfusion was interrupted because of a severe reaction. During the five weeks which preceded the patient's death he was given a total of seventeen blood transfusions. Five of these were preceded by the intravenous administration of diphenhydramine hydrochloride, and twelve were not. We believe that the drug may have aided in preventing reactions in this patient.

Case 5.—J. S., a Negro man aged 50, had chronic myelogenous leukemia. Following the administration of 150 cc. of a transfusion of compatible whole blood the patient had a severe reaction. On the next day the remainder of the same blood was given, preceded by 30 mg. of diphenhydramine hydrowere negative for pathogens. The blood cholesterol level was 253 mg., sugar 77 mg., urea nitrogen 16.4 mg. and nonprotein nitrogen 50 mg. per hundred cubic centimeters. The icterus index was 5.5 units. The hemoglobin level was 71 per cent (Sahli), the red blood cell count 4.04 millions, the white blood cell count 11,000, with segmented polymorphonuclears 16 per cent, stabs 3 per cent and lymphocytes 81 per cent. Urinalysis was normal except for a 2 plus sugar reaction.

A boy 2 years of age was given two "analbis" suppositories for otitis media and pharyngitis. About eighteen hours after the second suppository he went into severe collapse, followed the next day by fever and lethargy. He recovered after supportive measures and BAL therapy. The total dosage of BAL per kilogram of body weight is one of the largest ever given. This drug was administered at the suggestion of Dr. W. T. Salter, professor of pharmacology at the Yale University School of Medicine, in the belief that the unknown toxic agent might be a heavy metal. Whether its use was of any value is a matter of conjecture.

Case 4.—This case is contributed by Dr. Dorothy H. Andersen of Babies Hospital, New York, whose summary of the case is quoted.

A girl aged 2½ years had been well until Dec. 18, 1946, at which time there developed a cough, an elevation of temperature to 102 F., and an apparent infection of the upper part of the respiratory tract. She vomited twice. On examination she was moderately dehydrated; the pharynx was red and swollen; the liver was not palpable. She was given rectal fluids, acetylsalicylic acid and three suppositories containing the bismuth salt of diallylacetic acid in the course of about twenty-four hours. By December 20 she appeared well. At 3 a. m. December 21 she awoke suddenly and vomited. Later that day she was admitted to Babies Hospital because of drowsiness. She was semicomatose on admission; the abdomen was rounded and soft, the liver large and somewhat tender. She was treated with clyses and a transfusion, but on December 22 she became cyanotic, with slow Cheyne-Stokes respirations, and died. The highest temperature was 100 F.

The chief postmortem observations were a large liver weighing 720 Gm., which was mottled bright red and yellow, mild ascites (100 cc.) and edema of the peritoneal fat and connective tissue, decided edema of the gastric mucosa and extreme cerebral edema. There was no icterus. On microscopic examination, the liver showed acute early necrosis and the renal tubules contained much fat. There was a mild interstitial pneumonia, and examination of other organs revealed little that was unusual. There was no excess of bismuth in the liver. Comparison of slides from cases 1, 2 and 4 by Dr. Andersen and me revealed a close resemblance.

COMMENT

[illegible] itories bear[illegible] [illegible]he same lot number as those given to [illegible] 1, 2 [illegible] [illegible]d.[6] The bismuth content w[illegible] Gm. against .0225 Gm.). [illegible] found. The only [illegible]y acid in quantities [illegible] what is identified [illegible]dienecarboxylic [illegible]lylacetic acid.

It is not believed that bismuth is the agent responsible for the toxic action of these suppositories for several reasons. It was present in only small amounts in the organs on which analyses were performed (cases 2 and 4). There were no inclusion bodies in the renal tubular epithelium, nor was there any evident nephritis.[10] Finally, there is no convincing evidence that bismuth has ever caused hepatic damage of the type here described, the so-called bismuth hepatitis[11] doubtless being an instance of syringe transmission of virus hepatitis.

The type of damage to the liver seen at autopsy in these patients is not compatible with virus hepatitis or any of the usual hepatotoxins. The assumption that the heptadienecarboxylic acid or a contaminant thereof may be a hitherto undescribed hepatotoxin seems plausible.

Animal experimentation has not been revealing to date, largely due to inability to secure adequate material. Further studies are in progress in the Department of Pharmacology of the Yale University School of Medicine. The suppositories have been recalled from the market.[12]

CONCLUSION

Four cases are described in which profound collapse, fever, central nervous system symptoms and in 3 cases death followed the administration of suppositories containing the bismuth salt of heptadienecarboxylic acid (diallylacetic acid) for the treatment of infections of the upper part of the respiratory tract in children.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following article. Howard A. Carter, *Secretary.*

FEDERAL COMMUNICATIONS COMMISSION ANNOUNCES ITS REGULATIONS FOR SHORT WAVE DIATHERMY APPARATUS

After several years of discussions, conferences and hearings, as well as yeoman work on the part of the Radio Technical Planning Board of the radio industry, the Federal Communications Commission on May 9, 1947 released Public Notice number 7722 entitled "Order with Respect to Medical Diathermy and Industrial Heating Equipment and Notice of Proposed Rule Making with Respect to Miscellaneous Equipment."

This document assigned three frequencies, in harmonic progression, for medical diathermy and industrial heating. Channels are 13.66, 27.33 and 40.98 megacycles, corresponding to approximately 22, 11 and 7½ meters wavelength respectively. The widths of the channels are approximately 15, 320 and 40 kilocycles respectively. Harmonic and spurious radiations on frequencies other than those specified shall be suppressed, so that radiation does not exceed a strength of 25 microvolts per meter at a distance of 1,000 feet or more from the diathermy equipment causing such radiation.

Another channel has been assigned, namely 2,450 megacycles, corresponding roughly to 12.2 cm. wavelength. A frequency in the neighborhood of 6 megacycles will be announced later, and frequencies of 915, 5,850, 10,600 and 18,000 megacycles have also been allocated for industrial, scientific and medical use.

At present the commission has not found it necessary to make rules applicable to surgical diathermy.

[illegible] G. V., and Reynolds, W. J.: Bismuth Hepatitis—A Sur[illegible]undred and Twenty-One Cases, J. A. M. A. **120:** 343

[illegible] a letter dated Feb. 17, 1947 from Mr. Herbert P. [illegible]spector of Drugs, Devices and Cosmetics, State of [illegible]ood Commission.

The commission ruled that all diathermy equipment manufactured in the future shall meet these regulations if the equipment is to be used without a license. Manufacturers may now submit apparatus to the Laurel Laboratory of the Federal Communications Commission and receive "type-approval" of the equipment if it meets the rules and regulations. Using a type-approved apparatus, a physician need not obtain an operating license. If a physician is using existing equipment operating on a frequency not assigned, shielding must be employed and certification obtained. This rule refers to apparatus that was purchased prior to July 1, 1947.

Section 18.51 of the Rules and Regulations of the Federal Communications Commission under the caption "Existing Equipment" indicates that there are generally two methods of operating diathermy equipment in compliance with these rules for equipment manufactured after July 1, 1947. The first method is to operate within assigned frequency bands using equipment either "type-approved" or certified by a competent engineer in accordance with the applicable sections of the rules. The second method is to operate on any frequency provided the equipment is operated in a shielded room with a filtered power supply and all radiation on any frequency limited to 15 microvolts per meter at a distance of 1,000 feet or more from the diathermy equipment. Operation in this manner also requires certification by a competent engineer.

A physician owning and operating a diathermy apparatus manufactured prior to July 1, 1947 may continue to operate for a period of five years, provided the equipment does not interfere with authorized radio services. If interference is reported, the physician is responsible for eliminating the disturbance to radio communications. This may be accomplished in some instances by readjusting the existing diathermy appliance. If no means can be provided to eliminate the interference, then the physician becomes subject to the new rules and regulations. That is to say, he must screen the apparatus or acquire frequency controlled equipment.

More than ten years ago the Federal Communications Commission was requested by several radio communication agencies to formulate regulations to control man-made interference caused by diathermy equipment. When short wave diathermy was first marketed, the wavelengths employed were so short that the manufacturers did not anticipate any serious complications. In other words, that part of the radio spectrum used by diathermy was outside the region then generally employed for communications.

It was not long until the amateur radio operators were using these channels for communications, and they observed interference originating from diathermy equipment. The problem would not have been so confusing had these radiofrequency energies been restricted to two or three channels; but the manufacturers of diathermy equipment, being guided by the early clinical investigators, selected channels of several lengths for therapeutic purposes. Time and effort in research eventually established the therapeutic value of the physical agent. The Council on Physical Medicine reached the opinion after careful study that short wave diathermy was merely another means of applying heat to a patient and that it did not matter what wavelength between 30 and 5 meters was employed.

As radio communications expanded and more channels were needed for services such as ship to shore, airplanes to ground, police station to squad car and countless governmental and private services in the interests of the public, nearly all available channels have been assigned for such purposes.

Television was assigned channels and it became an important factor. Diathermy interfered with television in some instances, making the picture in the television receiver indistinguishable.

In 1939 the Federal Communications Commission called a meeting of the interested bodies, who met at Harkness Hall, Columbia University, New York. The representatives present entered into conversations with the object in view of reaching a solution to the problem.

While the manufacturers of diathermy equipment had no desire to make apparatus which would interfere with communications, there seemed to be no simple solution. Screened rooms were suggested, but they were high priced and inconvenient to install. Except in rare instances, screening diathermy apparatus to prevent interference was ruled out as expensive and cumbersome. There would be no interference if all of the radiofrequency energy generated by diathermy could be used efficiently for treatment purposes. Unfortunately, such diathermy apparatus has not been developed as will not radiate energy into space.

In the meantime, radiofrequency energy for industrial purposes had come into general use. Since the demands for communication channels were so great, considerable pressure was put on the Federal Communications Commission to provide as many channels as possible. Fortunately, all diathermy apparatus can be operated on the same radio channel or channels and there is no interference of one unit with another. Hence the interference problems of diathermy and industrial heating were considered one and the same by the commission.

Many installations of diathermy apparatus are used in steel buildings. The buildings themselves in many instances act as shields, and interference with radio communications is greatly reduced. It is relevant to mention that screening may not always act effectively as a shield when there are breaks or openings in the screen. Poor contacts along the door jamb may permit excessive amounts of leakage and thereby cause interference over long distances.

Probably the greatest problem of interference to radio communication is in the congested areas. For example, diathermy apparatus which is not controlled might be used in a physician's office in an apartment building while a resident in an adjacent apartment either on the same floor, upstairs or downstairs, might choose to operate a television receiver. The distance between a television set and the diathermy equipment might conceivably be only the width of the partition. An ordinary partition between the two apartments would be no barrier, since radio energy will go right through it. Without knowing, the physician might cause considerable annoyance to his neighbor. As a matter of fact, the neighbor might be a fellow physician. Indeed, the television receiver may belong to a physician who is causing the interference. Situations such as these might cause poor public relations.

Countless examples might be cited where interference occurs. Probably the most frequent at the present time is interference by stray radio frequency energy with police communications. Diathermy apparatus may be housed in a wooden building and the receivers on the police squad cars cruising in the streets will pick up the radio signal having the greatest field strength when frequency modulation receivers are employed. When amplitude modulation receivers are employed, serious interference will result even though the field strength of the signal radiated by the diathermy equipment is as low as one twentieth of the field strength of the police radio signal. The Federal Communications Commission has received several complaints of this interference with radio receivers on police mobile units.

Some discussion has been raised as to the relative merits of (1) the health of the nation and (2) the protection of the public by the police. While a physician may be treating disease, the police might be hampered by interference caused by a diathermy apparatus in protecting the property of the public. Fortunately, problems of this nature, if indeed they exist, can now be overcome by compliance with the rules and regulations of the Federal Communications Commission.

The medical profession and the manufacturers of diathermy are to be congratulated on the successful cooperation with the Federal Communications Commission and the representatives of other radio industries on reaching an amicable solution of this perplexing problem in the field of radio communications.

FRACTIONATION OF BLOOD FOR THERAPEUTIC PURPOSES

The value of blood in the prevention of disease rarely depends on the whole tissue. Cohn[1] points out that it more often depends on one or more of the cellular, protein or smaller organic constituents. The need is for quite different constituents of the blood in hemophilia or hypertension, measles or anemia, hemorrhage or infectious hepatitis, edema, shock or hypoproteinemia. The fractionation of plasma has made available the albumins for use in shock and the specific globulins of value in measles, hemophilia, blood typing and blood clotting. The method has also succeeded in separating many of the smaller molecules which are not free in the blood stream but are in highly specific, more or less labile combination with the larger proteins. The fractionation process[2] developed at Harvard Medical School yields all the components of human plasma in five major fractions. The physicochemical system on which the separation depends involves the principle determining electrostatic interactions between proteins and neutral salts, which generally lead to increased solubility, and interactions with less polar organic liquids, which generally lead to precipitating action. The balance between these forces has made possible the definition of conditions leading to far sharper separations than had previously been possible.

The method applied to plasma yields fibrinogen, which is the structural element of blood clotting and is concentrated in fraction I. All the prothrombin, which, converted to thrombin, transforms fibrinogen into fibrin, all the immune globulins for which tests have been carried out, the isohemagglutinins and Rh antibodies, and probably many other components of plasma which are not yet recognized are contained in fractions II and III. The remaining globulins are concentrated in fraction IV.

The protein fraction of blood plasma known as gamma globulin has, according to Stokes,[3] assumed a greatly enhanced significance. By the method of separation of this fraction a number of antibodies in adult blood plasma against foreign protein antigens such as viruses, bacteria, toxins and pollens has been obtained. The process of fractionation of gamma globulin not only separates but also concentrates the antibodies. The concentration of antibodies in the gamma globulin thus prepared is about twenty-five times that of normal pooled plasma. The plasma pools developed by the American Red Cross showed a surprisingly uniform titer of antibodies against the infectious agents endemic to the geographic area in which the blood donor resides. Stokes points out that following the influenza A epidemic of December 1943 the gamma globulins from all areas of the United States gave evidence of a general increase in the antibodies against the influenza A virus. A direct relationship between the height of such antibodies and individual resistance to influenza A has been demonstrated. The general level of donor's antibodies in any population may thus provide an indication of its susceptibility to the epidemic disease as well as evidence of a recent epidemic wave of influenza. Stokes calls attention to the fact that many epidemic diseases of childhood gradually immunize the general population, both by apparent and by inapparent cases, and leave in passage considerable amounts of antibodies in adult plasma. When such adult plasma is pooled from thousands of individuals it probably contains fairly uniform titers of antibodies. Gamma globulin from fractionated pools of plasma concentrates and preserves such antibodies in a readily usable form, which thus far apparently has been free from the danger of serum hepatitis.

Minot and Taylor[4] point out that fractions I, II and III of Cohn's fractions showed antihemophilic activity in studies made in vitro. The injection of preparations of fraction I was comparable in antihemophilic effect to that obtained following the injection of whole blood or plasma. These authors also point out that, in hemophilia, control of local hemorrhage is as important as the control of the blood coagulation time. Antihemophilic globulin has some hemostatic properties. Its action, however, is a matter of minutes to develop. On the other hand, thrombin preparations, which act directly on fibrinogen to produce fibrin clots, require only seconds to produce this effect. For this reason Minot and Taylor believe that thrombin is an ideal hemostatic agent. Preparations rich in prothrombin can be obtained by suitable fractionation of the plasma globulins. Prothrombin can be converted to thrombin by action with tissue thromboplastin derived from brain, lung, placenta or other tissues. The thrombin so obtained may be spread on or impregnated into sterile gauze, fibrin foams or absorbable cellulose and applied with pressure to the bleeding point. A thrombin preparation has been made by Parfentjev from rabbit plasma by salting out procedures not requiring activation with thromboplastin. Pohle and Taylor[5] prepared a similar product from the plasma of swine, steers and human beings, which, according to the authors, is an extremely potent hemostatic agent.

Normal human-serum albumin was primarily developed in response to an urgent request from the armed forces as a blood substitute for use in traumatic shock. Because its chemical properties make possible its distribution in a stable, concentrated solution, it is compact to transport and convenient to use. Experience during the war has demonstrated that optimal treatment of traumatic shock requires the use of whole blood to avoid the anemia which develops if plasma or albumin is administered for replacement. Serum albumin is useful for emergency supportive therapy. In hypoproteinemic edema concentrated low salt albumin furnishes exactly the combination of properties needed for rational therapy. In cirrhosis of the liver, intravenous albumin in doses of 25 to 50 Gm. daily in addition to an adequate diet will raise the serum albumin level to normal in one to two weeks. This change in serum proteins, according to Janeway,[6] is associated with an increase in sense of well being, disappearance of peripheral edema and some diminution of ascites.

PECULIARITIES OF THE CIRCULATION IN THE KIDNEYS AND LIVER

The kidneys, most marvelous anatomic structures in the body in Dock's[1] opinion, work best while we sleep. Under such basal conditions their blood flow and work of excretion are maximal. When the body is violently active or under stress imposed by shock or hemorrhage, excretion and blood flow fall to extremely low levels.[2] This paradoxical behavior was a remarkable discovery made by means of modern technics for measuring blood flow.

The extra oxygen consumed by the kidneys when the diet is changed from low protein to high protein is too small to be detected, and yet this change in diet leads to hypertrophy of the kidneys. In some types of renal injury the kidneys may be seriously jeopardized by a diet which supplies both urea and aromatic acids. The kidneys secrete aromatic acids five times as effectively as they filter off and concentrate urea.[3] It may be that aromatic acids stimulate hypertrophy and the increase in blood flow noted at the onset of hypertrophy. The blood flow, which is many times greater than necessary to supply the oxygen requirements of the kidneys, varies with the need to excrete deleterious substances. Infinitesimal amounts of fever producing substances, for example, evoke maximal renal flow.

Studies on shock have thrown new light on renal hypertension. A decrease in blood flow due to shock or to a clamp on the renal artery leads to remarkable events,[4] the most surprising of which is a decrease in renal metabolism and oxygen use roughly proportional to the decrease in blood flow. Thus, Dock points out, the kidneys not only work while we sleep but they sleep when we are struggling to maintain life. When the blood flow is first arrested and later released, the vascular bed of the kidney does not widely dilate as it does in other viscera. This inhibition of renal metabolism protects the kidney even from many hours of ischemia, whereas other organs are seriously damaged by shorter periods of arterial block. A few minutes of ischemia will practically destroy the brain.

Renal vasoconstriction occurs after hemorrhage, heart failure, when we suffer pain, fear or anxiety, and even when the erect posture is assumed, thus decreasing the cardiac output. Shock apparently leads to the release in the kidney of an inhibitor of renal metabolism that also causes vasoconstriction. The mechanism for reducing renal metabolism and causing renal vasoconstriction is set in play by lowering the renal arterial pressure or by raising the interstitial pressure. This mechanism can be set off, Dock believes, only by a sensitive structure in the vascular bed of the kidneys. It has been suggested[5] that the renal pressor mechanism is related to peculiar cells in the afferent arteriole of each glomerulus and the plaque of closely crowded epithelial cells in the distal convolution at the point where it touches the glomerular hilus. This structure shows mitotic figures, unusual cytoplasmic granules and hypertrophy in animals subjected to acute renal ischemia. Such peculiar tissue has been found to be hypertrophied in men who have been in shock for several days before death. Photomicrographs of such changes are on file at the Army Medical Museum. In the process of evolution this mechanism apparently was provided in relation to shock and hemorrhage, which are common hazards of all mammals living under natural conditions.

FRACTIONATION OF BLOOD FOR THERAPEUTIC PURPOSES

The value of blood in the prevention of disease rarely depends on the whole tissue. Cohn[1] points out that it more often depends on one or more of the cellular, protein or smaller organic constituents. The need is for quite different constituents of the blood in hemophilia or hypertension, measles or anemia, hemorrhage or infectious hepatitis, edema, shock or hypoproteinemia. The fractionation of plasma has made available the albumins for use in shock and the specific globulins of value in measles, hemophilia, blood typing and blood clotting. The method has also succeeded in separating many of the smaller molecules which are not free in the blood stream but are in highly specific, more or less labile combination with the larger proteins. The fractionation process[2] developed at Harvard Medical School yields all the components of human plasma in five major fractions. The physicochemical system on which the separation depends involves the principle determining electrostatic interactions between proteins and neutral salts, which generally lead to increased solubility, and interactions with less polar organic liquids, which generally lead to precipitating action. The balance between these forces has made possible the definition of conditions leading to far sharper separations than had previously been possible.

The method applied to plasma yields fibrinogen, which is the structural element of blood clotting and is concentrated in fraction I. All the prothrombin, which, converted to thrombin, transforms fibrinogen into fibrin, all the immune globulins for which tests have been carried out, the isohemagglutinins and Rh antibodies, and probably many other components of plasma which are not yet recognized are contained in fractions II and III. The remaining globulins are concentrated in fraction IV.

The protein fraction of blood plasma known as gamma globulin has, according to Stokes,[3] assumed a greatly enhanced significance. By the method of separation of this fraction a number of antibodies in adult blood plasma against foreign protein antigens such as viruses, bacteria, toxins and pollens has been obtained. The process of fractionation of gamma globulin not only separates but also concentrates the antibodies. The concentration of antibodies in the gamma globulin thus prepared is about twenty-five times that of normal pooled plasma. The plasma pools developed by the American Red Cross showed a surprisingly uniform titer of antibodies against the infectious agents endemic to the geographic area in which the blood donor resides. Stokes points out that following the influenza A epidemic of December 1943 the gamma globulins from all areas of the United States gave evidence of a general increase in the antibodies against the influenza A virus. A direct relationship between the height of such antibodies and individual resistance to influenza A has been demonstrated. The general level of donor's antibodies in any population may thus provide an indication of its susceptibility to the epidemic disease as well as evidence of a recent epidemic wave of influenza. Stokes calls attention to the fact that many epidemic diseases of childhood gradually immunize the general population, both by apparent and by inapparent cases, and leave in passage considerable amounts of antibodies in adult plasma. When such adult plasma is pooled from thousands of individuals it probably contains fairly uniform titers of antibodies. Gamma globulin from fractionated pools of plasma concentrates and preserves such antibodies in a readily usable form, which thus far apparently has been free from the danger of serum hepatitis.

Minot and Taylor[4] point out that fractions I, II and III of Cohn's fractions showed antihemophilic activity in studies made in vitro. The injection of preparations of fraction I was comparable in antihemophilic effect to that obtained following the injection of whole blood or plasma. These authors also point out that, in hemophilia, control of local hemorrhage is as important as the control of the blood coagulation time. Antihemophilic globulin has some hemostatic properties. Its action, however, is a matter of minutes to develop. On the other hand, thrombin preparations, which act directly on fibrinogen to produce fibrin clots, require only seconds to produce this effect. For this reason Minot and Taylor believe that thrombin is an ideal hemostatic agent. Preparations rich in prothrombin can be obtained by suitable fractionation of the plasma globulins. Prothrombin can be converted to thrombin by action with tissue thromboplastin derived from brain, lung, placenta or other tissues. The thrombin so obtained may be spread on or impregnated into sterile gauze, fibrin foams or absorbable cellulose and applied with pressure to the bleeding point. A thrombin preparation has been made by Parfentjev from rabbit plasma by salting out procedures not requiring activation with thromboplastin. Pohle and Taylor[5] prepared a similar product from the plasma of swine, steers and human beings, which, according to the authors, is an extremely potent hemostatic agent.

Normal human-serum albumin was primarily developed in response to an urgent request from the armed forces as a blood substitute for use in traumatic shock. Because its chemical properties make possible its distribution in a stable, concentrated solution, it is compact to transport and convenient to use. Experience during the war has demonstrated that optimal treatment of traumatic shock requires the use of whole blood to avoid the anemia which develops if plasma or albumin is administered for replacement. Serum albumin is useful for emergency supportive therapy. In hypoproteinemic edema concentrated low salt albumin furnishes exactly the combination of properties needed for rational therapy. In cirrhosis of the liver, intravenous albumin in doses of 25 to 50 Gm. daily in addition to an adequate diet will raise the serum albumin level to normal in one to two weeks. This change in serum proteins, according to Janeway,[6] is associated with an increase in sense of well being, disappearance of peripheral edema and some diminution of ascites.

PECULIARITIES OF THE CIRCULATION IN THE KIDNEYS AND LIVER

The kidneys, most marvelous anatomic structures in the body in Dock's [1] opinion, work best while we sleep. Under such basal conditions their blood flow and work of excretion are maximal. When the body is violently active or under stress imposed by shock or hemorrhage, excretion and blood flow fall to extremely low levels.[2] This paradoxical behavior was a remarkable discovery made by means of modern technics for measuring blood flow.

The extra oxygen consumed by the kidneys when the diet is changed from low protein to high protein is too small to be detected, and yet this change in diet leads to hypertrophy of the kidneys. In some types of renal injury the kidneys may be seriously jeopardized by a diet which supplies both urea and aromatic acids. The kidneys secrete aromatic acids five times as effectively as they filter off and concentrate urea.[3] It may be that aromatic acids stimulate hypertrophy and the increase in blood flow noted at the onset of hypertrophy. The blood flow, which is many times greater than necessary to supply the oxygen requirements of the kidneys, varies with the need to excrete deleterious substances. Infinitesimal amounts of fever producing substances, for example, evoke maximal renal flow.

Studies on shock have thrown new light on renal hypertension. A decrease in blood flow due to shock or to a clamp on the renal artery leads to remarkable events,[4] the most surprising of which is a decrease in renal metabolism and oxygen use roughly proportional to the decrease in blood flow. Thus, Dock points out, the kidneys not only work while we sleep but they sleep when we are struggling to maintain life. When the blood flow is first arrested and later released, the vascular bed of the kidney does not widely dilate as it does in other viscera. This inhibition of renal metabolism protects the kidney even from many hours of ischemia, whereas other organs are seriously damaged by shorter periods of arterial block. A few minutes of ischemia will practically destroy the brain.

Renal vasoconstriction occurs after hemorrhage, heart failure, when we suffer pain, fear or anxiety, and even when the erect posture is assumed, thus decreasing the cardiac output. Shock apparently leads to the release in the kidney of an inhibitor of renal metabolism that also causes vasoconstriction. The mechanism for reducing renal metabolism and causing renal vasoconstriction is set in play by lowering the renal arterial pressure or by raising the interstitial pressure. This mechanism can be set off, Dock believes, only by a sensitive structure in the vascular bed of the kidneys. It has been suggested [5] that the renal pressor mechanism is related to peculiar cells in the afferent arteriole of each glomerulus and the plaque of closely crowded epithelial cells in the distal convolution at the point where it touches the glomerular hilus. This structure shows mitotic figures, unusual cytoplasmic granules and hypertrophy in animals subjected to acute renal ischemia. Such peculiar tissue has been found to be hypertrophied in men who have been in shock for several days before death. Photomicrographs of such changes are on file at the Army Medical Museum. In the process of evolution this mechanism apparently was provided in relation to shock and hemorrhage, which are common hazards of all mammals living under natural conditions.

In contrast to the kidney, the liver is one of the simplest glandular structures. Its oxygen uptake is determined by its metabolic activity. The rise in total metabolism after a meal of high protein content is due almost entirely to intense hepatic activity. Clinicians therefore might reason that a high protein diet would retard the recovery of a diseased liver by increasing its metabolic activity; experience shows however that a high protein diet is beneficial in hepatitis and cirrhosis, even though it makes the liver work harder.

As is well known, the blood flow to the liver comes from two sources—the portal vein and the hepatic artery. The portal flow may be diverted wholly into the inferior vena cava without damage to the liver; and, in dogs, ligation of the hepatic artery causes no apparent damage. Such ligation may have serious effects however on a patient with chronic biliary tract disease. Cirrhosis provides the chief interest in the vascular bed of the liver. While anatomic studies indicate that the arterioles and the portal venules enter the sinuses of the liver lobule separately, the rate of perfusion through the normal portal vein drops a third when pressure in the hepatic artery is raised from 0 to 100 mm. during a double perfusion with oil with portal pressure at 20 mm. In alcoholic cirrhosis the portal blood flow was found to fall 78 per cent when blood flow at 100 mm. pressure was established in the hepatic artery. Perfusion studies made by Dock were interpreted as confirming Herrick's[6] report of greatly increased hepatic arterial inflow in some types of cirrhosis. This is believed to be due to the development of numerous minute arteriovenous fistulas analogous to the spider angiomas in the skin.

Current Comment

GOITER PREVENTION

McClendon and Hathaway[1] demonstrated in analyses made in 1924 that the iodine content of the food in the nongoitrous regions may be 100 per cent higher than that in the goitrous regions. They calculated from the quantity of iodine in the normal thyroid gland and the rate at which a person may drink water that in goitrous regions the iodine should be added up to 1,000 parts per hundred billion or 1 part per hundred million. This can be accomplished by adding 45 Gm. of sodium iodide per million gallons of water. Beaumont and Karns were able to increase the iodine content of turnips by the application of potassium iodide to the soil. The iodide treated plants contained 441 and 950 parts per billion of iodine in the roots and tops respectively, against 165 and 441 parts in chloride treated plots. Whether or not these quantities of iodine in food have therapeutic value has been partly answered by the experiments of Hunziker in Switzerland. Hunziker added potassium iodide to the fertilizer used for the garden from which his family was supplied with such vegetables as spinach, rhubarb, cabbage, lettuce and beans. The iodized vegetables were served to his 5 children ranging in age from 3 to 8 years. As a control 5 children from another family were supplied with vegetables which were raised on soil that was not iodized. Hunziker's graphs of the measurements of the circumference of the neck in the thyroid region show the beneficial influence of the iodized vegetables on the growth of the thyroid gland. Zwick[2] called attention in 1933 to the fact that the administration of even such minute quantities of iodine as are needed for goiter prophylaxis may be followed in some instances by a follicular eruption of pustular character. These cutaneous lesions must be differentiated from the juvenile form of acne, which they resemble. Iodide acne seems to occur more frequently since our drinking water is chlorinated, a circumstance which Zwick explains by the fact that all halogens act as follicular irritants. The possibility of a follicular eruption does not constitute per se a contraindication to attempts at goiter prevention by means of adding iodine to the water supply or to the soil in which vegetables are raised.

STABILITY OF PROTHROMBIN

The current belief that prothrombin disappears rapidly from blood or plasma stored at low temperatures is based on numerous chemical analyses by the generally used one stage method. In this method the time required for clotting after the addition of a large amount of thromboplastin is taken as a measure of prothrombin concentration. Studies based on the use of the more elaborate two stage method of analysis show, in contrast, that prothrombin disappears relatively slowly from stored blood. The latter procedure has been shown to be the more reliable by Ware, Guest and Seegers[1] by actual isolation of the amount of prothrombin indicated in the analysis. Unreliable values for prothrombin obtained by the one stop method of analysis may be attributed to the interfering action of a substance, recently reported to be present in plasma,[2] which accelerates the rate of activation of prothrombin to thrombin by thromboplastin and calcium ions. Crude preparations of this substance have been obtained by chemical fractionation, but the chemical structure is not yet known. Another new factor reported to be present in plasma by these same investigators has been shown to protect prothrombin. Purified prothrombin is unstable at room temperature, whereas the prothrombin in plasma is comparatively stable. Also purified prothrombin is stabilized when it is dissolved in plasma. Progress is steadily being made in preparing in pure form the many substances required for normal blood clotting and in reproducing the clotting reaction in the test tube under strictly controlled conditions.

ORGANIZATION SECTION

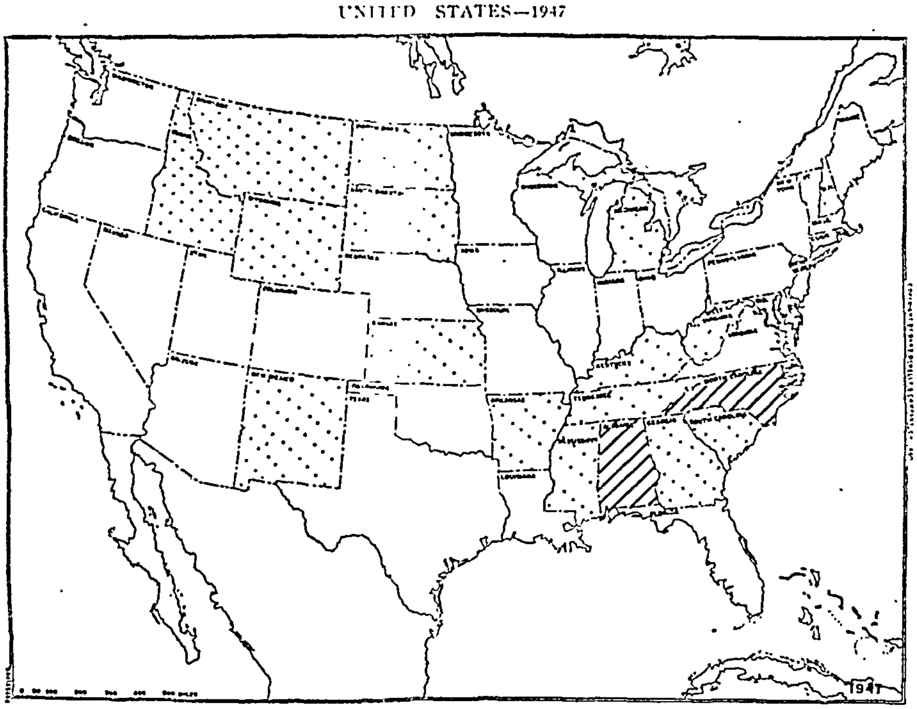
Bureau of Information

LOCATION OF PHYSICIANS

Virginia Shuler
Chicago

This is the tenth and last of a series of charts showing the trend in locations of physicians from April 1946 to January 1947.

After all the doctors have returned from the service and have established their practices, many areas still will be lacking in medical personnel, chiefly because these communities are financially unable to support a doctor or have inadequate hospital facilities. One of the ten points of the American Medical Association's program for extending to all people in all communities the best possible medical care recognizes federal aid to states where definite need is demonstrated to be administered by the proper local agencies of the states involved, with the help and advice of the medical profession. With this in mind, the Hill-Burton hospital survey and construction program was favored by the Association especially for its effect on rural practice. It is most important that these hospitals and health centers maintain at all times high medical standards. In order to attract physicians into areas where they are needed, physicians must have reasonable assurance of economic security, satisfactory medical facilities and an opportunity to practice medicine at its best.



Population, based on 1943 estimated Census figures, per physician (excludes retired and not in practice) by state.

Key: Physician-population ratio by state: plain area 1-999, dotted area 1,000-1,499, striped area 1,500-2,999, checked area 3,000 and over.

The Hospital Survey and Construction Program

Last summer Congress passed the Hospital Survey and Construction Act. This legislation has two broad purposes: first, to help the states find out what their hospital facilities are and, second, to help build new hospitals or additions where they are needed most. To accomplish this twofold aim, the act authorizes $3,000,000 in federal funds to assist with the survey and planning and $75,000,000 a year for the next five years to assist with construction.

Probably the most forward looking feature of this legislation is its requirement that the states survey their existing facilities and plan construction where the need is greatest. Obviously, the most urgent need is in our rural sections, and for this reason priority is being given to those areas. However, there are limitations to this program which will affect rural communities the most. The first is the requirement that, for every dollar of federal funds spent on hospital construction, the community itself must put up two dollars. The second is the matter of maintenance and operation; no federal funds are provided for this purpose. Hospitals are complex institutions, expensive to build and maintain, and, if rural communities are to realize the benefits of this legislation, many of them will need additional help.

Five states have already recognized this situation and have passed laws authorizing state funds to aid local communities in hospital construction. Two states have gone a step further by appropriating money to help with the maintenance once the hospitals are built. Other states are considering similar legislation.

In the year since the passage of the hospital act great progress has been made. All states and territories have started, and some have completed, their surveys. By June 30 three states had submitted their state plans, and reports indicated that nearly all the states would have theirs ready by the end of this year. So that construction can start immediately, Congress authorized an arrangement which makes $75,000,000 available for hospital building during the year ending June 30, 1948. These funds may be used not only for hospitals but for health centers, laboratories, clinics and other medical facilities.

VANE M. HOGE, M.D., Medical Director;
Chief, Division of Hospital Facilities,
U. S. Public Health Service.

Medical Service Program

To develop the Ten Point Program of the American Medical Association the Council on Medical Service believes that any program for the medical care of the American people must be built from the bottom up—and not be imposed from the top down. Hence the importance of this state by state study is obvious. Of major importance in this program was the nationwide development of voluntary prepayment medical care plans. This voluntary program has now spread to thirty-six states and the District of Columbia. All but one of the remaining states are seriously working on a prepayment program. Enrolment in these plans is steadily growing, and special attention is now being directed toward the rural areas.

Thirty-seven of sixty-one medical society plans have started a rural enrolment program. Twenty-one of these plans have enrolled 385,922 persons from these areas. Enrolment figures are steadily increasing, as also is the number of plans undertaking enrolment in rural areas.

Assistance is extended to farm groups and to others in rural areas not associated with groups for enrolment on a community basis. Local health councils with representation from professional societies and from civic, farm and industrial groups are preparing to spearhead the further development of voluntary prepayment medical care plans.

The Council on Medical Service has just completed a special brochure on "Medical Care Prepayment Plan Development Through a Local Health Council," which will be ready for distribution soon. This outlines a plan for organization, lists the functions for a local health council and suggests ways to obtain enrolment in rural areas. This local activity with medical society guidance is progressively building toward better medical care for all people.

To get action from the profession on the Ten Point Program, regional conferences have been held by the Council throughout the country and many state and county medical societies have inaugurated programs of their own or have taken the Ten Point Program and adapted it to their own local needs. To date these conferences have consisted largely of discussion by key physicians. A new development in this will mark the regional conference of the Southeastern states to be held in Atlanta, Ga., in October to consider "Health Problems of the South." Leaders in farm, educational and industrial life of the South, as well as physicians, will be on the program.

The problem of medical service is not static. It is complex. It demands cooperation. As soon as progress is made in one segment of the problem, other problems will arise, for medical progress brings medical problems.

Under the leadership of American medicine much is being done to solve these problems. Rural health conferences are being held, health councils formed, studies being made in child health, in old age. From all angles surveys are projected. American medicine is attacking these problems—no matter how difficult—wholeheartedly, efficiently, tirelessly and often successfully.

THOMAS A. HENDRICKS, Secretary,
Council on Medical Service,
American Medical Association.

Washington Letter

(From a Special Correspondent)

Sept. 3, 1947.

Committee to Coordinate Government Research

A report by Presidential Assistant John R. Steelman as chairman of the President's Scientific Research Board advocated an expenditure of two billion dollars a year on scientific research by 1957. Commenting on it, President Truman announced that he would shortly name a federal committee to aid coordination of government research programs. The report advocated formation of a National Science Foundation, although Mr. Truman had vetoed the bill passed by Congress last session creating such a foundation on the ground that it centered too much authority in a part time committee of scientists. Mr. Steelman's report also urged heavier emphasis on basic research and medical research and recommended that military research be continued at a high level for the next five years. Other proposals: a federal program of assistance to undergraduate and graduate students in science as part of an overall national scholarship and fellowship program to deal with scientific manpower shortages; federal assistance to universities and colleges in laboratory facilities and scientific assistance; assistance to European laboratories as part of a program of peaceful aid. The report stated that the Soviet Union's 1947 budget provides $1,200,000,000 for research and development, and Russia has adopted a five year program to produce 140,000 engineers and scientists each year. The report blamed England's lag in technological developments for upsetting the balance of power in Europe, causing two world wars. Discontinuance of a flow of scientific information from other countries, because "Europe's laboratories are still blacked out," was described by Mr. Truman as "an emergency and a challenge."

Ask Investigation of Veterans Administration Program

Louis E. Starr, Veterans of Foreign Wars commander, urged an immediate joint study by a congressional committee and a group of war veterans of the Veterans Administration hospital building program, which he said was "hopelessly adrift." He urged that the study be ready for consideration by Congress when the next session opens in January. He charged that the VA hospital waiting list contains 19,000 names and claimed that the program to establish 150,000 hospital beds by 1948 is two years behind schedule.

President Requests Job Assistance for the Physically Handicapped

Federal, state and local officials have been asked by President Truman to cooperate in a program aimed at finding jobs for physically handicapped persons. The request was made during signing of the proclamation designating October 5 to 11 as "National Employ the Physically Handicapped Week."

Coming Medical Meetings

American Academy of Neurological Surgery, Colorado Springs, Broadmoor Hotel, Oct. 9-11. Dr. T. C. Erickson, 1300 University Ave., Madison 5, Wis., Secretary.

American Academy of Ophthalmology and Otolaryngology, Chicago, Palmer House, Oct. 12-17. Dr. W. L. Benedict, 102 Second Ave. S.W., Rochester, Minn., Secretary.

American Anti-Arthritis Association, Del Mar, Calif., Oct. 4-5. Dr. Robert T. Pottenger, 65 N. Madison Ave., Pasadena, Calif., Secretary.

American Association of Medical Record Librarians, New York, Hotel Commodore, Sept. 7-12. Mrs. Adaline Hayden, 18 E. Division St., Chicago, Executive Secretary.

American Clinical and Climatological Association, Colorado Springs, Oct. 13-15. Dr. James Bordley III, Johns Hopkins Hospital, Baltimore 5, Secretary.

American College of Surgeons, New York, Waldorf-Astoria Hotel, Sept. 8-12. Dr. Paul B. Magnuson, 40 E. Erie St., Chicago 11, Secretary.

American Congress on Obstetrics and Gynecology, St. Louis, Municipal Auditorium, Sept. 8-12. Mr. Karl S. Richardson, 24 West Ohio St., Chicago, Business Manager.

American Hospital Association, St. Louis, Sept. 22-25. Mr. George P. Bugbee, 18 E. Division St., Chicago, Exec. Secretary.

American Public Health Association, Atlantic City, Oct. 6-10. Dr. Reginald M. Atwater, 1790 Broadway, New York 19, Executive Secretary.

American Roentgen Ray Society, Atlantic City, Sept. 16-19. Dr. H. Dabney Kerr, University Hospitals, Iowa City, Secretary.

Central Neuropsychiatric Association, Galveston, Texas, Oct. 17-18. Dr. William C. Menninger, 3617 W. Sixth Ave., Topeka, Kans., Secretary.

Colorado State Medical Society, Denver, Shirley-Savoy Hotel, Sept. 17-20. Mr. Harvey T. Sethman, 1612 Tremont Place, Denver 2, Executive Secretary.

Connecticut Clinical Congress, New Haven, Sept. 16-18. Dr. Francis G. Blake, 258 Church St., New Haven, Chairman.

Delaware, Medical Society of [illegible] Dr. John F. Hynes, Memorial Hospital, [illegible]

District of Columbia, Medical [illegible] Oct. 6-8. Mr. Theodore Wiprud, 1718 M [illegible], Secretary.

International College of Surgeo [illegible] Palmer House, Sept. 29-Oct. 2. Dr. Louis J. Gariepy, 16401 Grand River Ave., Detroit 27, Secretary.

Inter-State Postgraduate Medical Association of North America, St. Louis, Public Auditorium, Oct. 14-17. Dr. Tom B. Throckmorton, 406 Sixth Ave., Des Moines, Iowa, Secretary.

Kentucky State Medical Association, Louisville, Sept. 29-Oct. 2. Dr. P. E. Blackerby, 620 S. Third St., Louisville 2, Secretary.

Michigan State Medical Society, Grand Rapids, Pantlind Hotel, Sept. 23-26. Dr. L. Fernald Foster, 2020 Olds Tower, Lansing 8, Secretary.

Mississippi Valley Conference on Tuberculosis, Chicago, Edgewater Beach Hotel, Sept. 8-10. Mr. Donald E. Pratt, 411 W. Tenth St., St. Louis 1, Secretary.

Mississippi Valley Medical Society, Burlington, Iowa, Oct. 1-3. Dr. Harold Swanberg, 510 Maine St., Quincy, Ill., Secretary.

Pennsylvania, Medical Society of the State of, Pittsburgh, Hotel William Penn, Sept. 15-18. Dr. Walter F. Donaldson, 500 Penn Avenue, Pittsburgh 22, Secretary.

Southern Psychiatric Association, Birmingham, Ala., Oct. 13-14. Dr. Newdigate M. Owensby, 384 Peachtree St. N.E., Atlanta, Ga., Secretary.

Utah State Medical Association, Salt Lake City, Sept. 11-13. Dr. Ray T. Woolsey, 316 Atlas Bldg., Salt Lake City 1, Secretary.

Vermont State Medical Society, Burlington, Hotel Vermont, Oct. 1-3. Dr. Theodore H. Harwood, 128 Merchants Row, Rutland, Secretary.

Virginia, Medical Society of, Roanoke, Oct. 13-15. Miss Agnes V. Edwards, 1200 E. Clay St., Richmond 19, Secretary.

Washington State Medical Association, Seattle, Olympic Hotel, Sept. 28-Oct. 1. Dr. Harold E. Nichols, 327 Cobb Building, Seattle, Secretary.

Wisconsin, State Medical Society of, Milwaukee, Oct. 6-8. Mr. Charles H. Crownhart, 110 E. Main St., Madison 3, Secretary.

World Medical Association, Paris, France, Sept. 17-20. Dr. Charles Hill, B. M. A. House, Tavistock Sq., London, W. C. 1, England, and Dr. P. Cibrie, 60 boulevard de Latour-Maubourg, Paris 7e, France, Joint Secretaries

GOVERNMENT SERVICES

VETERANS ADMINISTRATION

RESIDENCY TRAINING

The Veterans Administration is making every effort to encourage doctors who complete residency training in one of its hospitals to accept full time probational appointments in its department of medicine and surgery, Dr. Paul R. Hawley, chief medical director, said August 18. On the satisfactory completion of three years' probational work, appointments are made permanent. These doctors will be placed, if possible, in positions where they may practice their specialties and best serve ill and disabled veterans, Dr. Hawley added.

The Veterans Administration offers the guidance of certified specialists to doctors who will serve in Veterans Administration hospitals both during and after completion of residency training. Guidance in the field of psychiatry also is offered in mental hygiene clinics where the chief of clinic has not been certified by the American Board of Neurology and Psychiatry, provided the chief is a capable specialist. In many fields, such as dermatology, ophthalmology and otolaryngology, guidance might also be received by doctors at regional offices The Veterans Administration has training programs under way in 62 of its 124 hospitals, with 1,770 residents studying for their specialty boards. This training program is a vital source for the recruitment of permanent doctors for the department of medicine and surgery and is an important feature of the program to provide eligible veterans with medical care "second to none"

FIFTEEN NEW VETERANS' HOSPITALS

The War Department announces that the army chief of engineers expects to advertise for bids for the construction of fifteen new Veterans Administration general hospitals, some of them within forty-five days, for which the working drawings have been completed. These hospitals will be located at:

Beckley, W. Va.	200 beds each
Clarksburg, W. Va.	
Grand Island, Neb.	
Poplar Bluff, Mo.	
Fort Wayne, Ind.	
Erie, Pa.	
Altoona, Pa.	
Newark, N. J.	1,000 beds
Little Rock, Ark.	500 beds each
Omaha	
Wilkes-Barre, Pa.	475 beds
Shreveport, La.	450 beds
Wilmington, Del.	300 beds
Iron Mountain, Mich.	250 beds each
Big Spring, Texas	

Of the other forty-nine hospitals included in the program undertaken by the army engineers for the Veterans Administration, the preliminary plans are at a stage where their revision can be made with a minimum of loss of time and effort. The engineers plan to slash about $100,000,000 off the present designs in accordance with the statement by General Bradley that present day prices make it necessary to modify the designs or obtain a large amount of additional building funds.

COMPENSATION PAYMENTS TO VETERANS WITH TUBERCULOSIS

The Veterans Administration will extend compensation payments to veterans who have been discharged from VA hospitals with arrested pulmonary tuberculosis but who need more time at home in which to recover sufficiently to take a job without endangering their health. The new plan announced by the Veterans Administration permits payment to such veterans on a totally disabled basis up to two years from date of discharge from any VA hospital while they remain under close medical supervision. Previously these payments were reduced by 50 per cent within six months of the veteran's discharge from the hospital. Now these veterans will be examined every six months and, if examination shows they are unable to resume employment, physicians will certify their findings so that the VA may determine whether to continue full compensation payments for an additional six months. This plan is expected to result in better control of arrested pulmonary tuberculosis among veterans and so reduce the necessity of hospitalizing them again. Many prominent tuberculosis specialists have advocated this action, it is said, and characterize it as one of the most promising advances in the care of tuberculosis by the Veterans Administration.

INCREASED ALLOWANCE TO VETERAN STUDENTS

A law passed by the last session of Congress provides for automatic increases effective September 1 in the minimum allowances received by the more seriously disabled veterans enrolled in educational and training courses under government sponsorship. The law provides that a veteran enrolled in a course under the Vocational Rehabilitation Act (Public Law 16) whose disability is 30 per cent or higher will receive $115 a month if he has no dependents, and $135 if he has one dependent. The old law allowed $105 and $115 respectively for the same two categories, and the lower figures will continue to apply to veterans with disabilities of less than 30 per cent. The new law also increases the allowance for additional dependents of veterans with disabilities of 30 per cent or more, the additional allowance for one child being increased from $10 to $20 a month, and the previous allowance of $7 a month for each additional child being increased to $15.

AIR CONDITIONED HOSPITAL AT FRESNO, CALIF.

The contract for $5,645,700 for the construction of the Veterans Administration Hospital at Fresno, Calif., which has been awarded, is the first contract made under the procedure developed by General Bradley, administrator of veterans affairs, and Lieut. Gen. Wheeler, army chief of engineers, calling for a revision of designs to meet a smaller budget. This 250 bed general hospital will be the only air conditioned one in the program undertaken by the army corps of engineers for the Veterans Administration.

LAUNDRY EQUIPMENT FOR HOSPITALS

The Army Corps of Engineers has awarded a contract for $3,236,067 for laundry equipment for sixty-one Veterans Administration hospitals. The equipment includes washing machines, drying tumblers, press units, extractors, marking machines and all other units that go to make a first class laundry.

PENSIONS FOR VETERANS OF CIVIL AND SPANISH-AMERICAN WARS

The Veterans Administration will pay a 20 per cent increase in non-service connected pensions for veterans of the Civil and Spanish-American wars and in death compensation to their dependents, effective in September. Some 113,000 veterans and 95,000 dependents of deceased veterans will benefit by the new law. It is estimated that the increase will total about $29,000,000 for the first year and that the cost will decline rapidly thereafter. Previously, payments ranged from less than $15 a month to $100 a month.

TESTS TO IMMOBILIZE BACTERIA IN HOSPITALS

The Veterans Administration is conducting an intensive pilot test in a New England hospital with an oil emulsion designed to immobilize bacteria in tuberculosis wards and hospitals. Blankets, linens and floors have been treated with a highly refined oil in order to trap settling bacteria and prevent their recirculation by air currents within the patients' rooms. Methods are also being studied to kill the trapped bacteria by means of chemicals or drugs. As yet the results of adding various compounds to the oil for this purpose have been disappointing. The purpose of the experiments is to reduce further the danger of Veterans Administration employees contracting tuberculosis and transmitting it to others.

THE AURAL REHABILITATION PROGRAM

About 30,000 World War II veterans with service connected hearing impairments will be eligible for the recently established rehabilitation program. Two Veterans Administration and two naval hospitals have been designated as centers where fenestration operations may be performed on veterans who stand a chance of regaining some degree of hearing through treatment. The Veterans Administration hospitals are in Los Angeles and San Francisco, and the naval hospitals are in Bethesda, Md., and Philadelphia.

HOSPITAL NEWS

Bids are being accepted by the Veterans Administration for the construction of a 564 bed neuropsychiatric addition to the hospital at Lebanon, Pa. This hospital now has 212 beds for medical and surgical cases and 265 beds for neuropsychiatric patients.

The Danville, Ill., Y. M. C. A. is cooperating with the Veterans Administration hospital in that city by offering its gymnasium facilities to patients able to take part in athletics.

A patient in the Veterans Administration hospital at Memphis, Tenn., paralyzed from the waist down coached employee basketball teams from a wheel chair, and the men's team won twelve out of the fifteen games.

The Veterans Administration in the Dallas, Texas, area has obtained more than two hundred bicycles from army surplus stocks for patients who have their physician's permission to ride them.

RESIDENCY TRAINING IN TUBERCULOSIS

For the first time the Veterans Administration is offering physicians residency type training in tuberculosis. This training will be available at VA hospitals at Alexandria, La., Excelsior Springs, Mo., Brecksville, Ohio, Oteen, N. C., and McKinney, Texas. Physicians serving in these residencies may earn credit toward the examinations of the American Board of Internal Medicine and its subspecialty board for pulmonary diseases.

PERSONAL

Dr. J. B. Floyd has resigned as director of the tuberculosis prevention work with the Kentucky State Health Service and has accepted a position as chief medical officer for Eastern Kentucky for the Veterans Administration, with headquarters at Lexington.

Dr. Walter B. Brown has been appointed clinical director of the Veterans Administration hospital at San Fernando, Calif. He is a graduate of Rush Medical College, Chicago, a veteran of World War II and formerly was chief of tuberculosis at the Veterans Administration hospital, Livermore, Calif.

Dr. James J. Raleigh has been assigned to the staff of the veterans' hospital at Sunmount, N. Y. Dr. Raleigh formerly was connected with the Berthold S. Pollak Hospital for Chest Diseases, Jersey City, N. J.

PUBLIC HEALTH SERVICE

EUROPEAN ARRIVALS MUST BE VACCINATED

Persons arriving from Europe are now required to present a certificate showing that they have been successfully vaccinated against smallpox within the last three years or show physical evidence that they have had smallpox, the U. S. Public Health Service has announced. Travelers who cannot prove immunity to smallpox must either consent to an immediate vaccination or remain under observation of quarantine officials until the incubation period for the disease is past. This period will not exceed fourteen days after arrival. Increased air travel, which results in travelers reaching the United States before outbreaks of smallpox in foreign countries can be reported to quarantine officials, necessitated the new immunization requirement. As a further protection, arrangements are being made with the transportation industry to refuse to sell tickets to persons who cannot show proof of smallpox immunity.

AWARDS AND COMMENDATIONS

Dr. Thomas Parran Jr.

The United States of America Typhus Commission Medal has been awarded to Dr. Thomas Parran Jr., Surgeon General, U. S. Public Health Service, who, according to the citation, rendered exceptionally meritorious service in connection with the work of the United States of America Typhus Commission during the period July 1942 to June 30, 1946. Through his wisdom, special knowledge, advice and influence, he contributed to the commission's investigations and control of typhus fever in the United States and in theaters of operation overseas. World renowned leader in public health, Dr. Parran has inspired and helped to create a new era in worldwide typhus control. Dr. Parran graduated from Georgetown University School of Medicine, Washington, D. C., in 1915 and entered the military service March 26, 1917.

MISCELLANEOUS

SALE OF SURPLUS GOVERNMENT PROPERTY

The War Assets Administration is conducting sales of surplus government property, in purchasing which physicians who are veterans have certain priorities. Items in a sale at the Army Base, Boston 10, are crutches, stretchers, beds, oxygen purifiers, electric oven or incubator, microscopic lamps and hand splints. The sale closes September 22. The Denver Regional Office, 728 15th Street, Denver 2, of the War Assets Administration is conducting a sale, beginning September 18, of various kinds of sterilizers, including those used for surgical instruments, dressings, utensils, hypodermic needles and water. Physicians who are veterans have certain priorities in these sales. Orders received after September 17 will be filled without regard to priorities. In this continuous fixed price sale, a deposit of at least 10 per cent of the total price offered must accompany all orders; $25 is the smallest deposit acceptable.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

ALABAMA

Postgraduate Seminar.—The Medical College of Alabama, Birmingham, and the committee on postgraduate study of the Medical Association of the State of Alabama are setting up a three day postgraduate seminar September 24-26 in the auditorium of the Nurses Home, City Hospital, Mobile. Among the subjects to be discussed, largely by men from the state, are recent advances in hematology, tumors, management of peptic ulcer, common surgical problems, urethane in the treatment of leukemia, the Wassermann test in private practice, cardiac emergencies, controversial points in the treatment of coronary occlusion and the nutritional anemias. All doctors are invited. There will be no registration fee.

ARKANSAS

Drs. Meschan and Reilly to Head Departments.—Full time heads of the departments of pediatrics and radiology, University of Arkansas School of Medicine, Little Rock, have been announced. Dr. Isadore Meschan, former instructor of radiology, Western Reserve University School of Medicine, Cleveland, became head of the department of radiology July 15. He is a graduate of Western Reserve University School of Medicine, 1939, and served in World War II. Dr. William A. Reilly, associate professor of pediatrics at the University of California Medical School, Berkeley-San Francisco, will head the department of pediatrics beginning September 1. A graduate of the University of California Medical School, Berkeley-San Francisco, 1927, he has served on the staffs of the University of California, San Francisco, Franklin and St. Mary's hospitals. From 1942 to 1946 he served in the medical corps, Army of the United States, in Africa, Italy and France.

CONNECTICUT

Clinical Congress.—The Connecticut State Medical Society and the Yale University School of Medicine, New Haven, will hold their twenty-second clinical congress September 16-18. The morning presentations will be given in the auditorium of the Yale University School of Law, and the afternoon panels and symposiums in the amphitheaters of the New Haven Hospital and the School of Medicine. Out of state speakers addressing the congress include:

Dr. Lester Dragstedt, Chicago, Vagotomy in the Treatment of Peptic Ulcer.
Ralph M. Kaufman, New York, Psychiatry in a General Hospital.
Dr. Frank W. Reynolds, Baltimore, Results of the Cooperative Clinic Study of the Treatment of Syphilis with Penicillin.
Dr. Raymond D. Adams, Boston, Treatment of Neurosyphilis.
Dr. Samuel M. Peck, New York, Epidemic Ringworm of the Scalp.
Dr. Howard Ulfelder, Boston, Use of the Vaginal Smear in the Diagnosis of Cancer.
Dr. Orvar Swenson, Boston, Congenital Anomalies Causing Obstruction in Gastrointestinal Tract.
Dr. James H. Means, Boston, Treatment of Thyrotoxicosis.
Dr. Wesley W. Spink, Minneapolis, Brucellosis.
Dr. Isadore Snapper, New York, Boeck's Sarcoid.
Dr. Franklin M. Hanger, New York, Liver Function Tests.
Dr. William Dameshek, Boston, Rationality in the Treatment of Anemia.
Dr. John M. Murray, Boston, Psychotherapy in General Practice and in Psychiatric Practice.

Tuesday's program includes panel discussions on Surgical Treatment of Peptic Ulcer, Treatment of Syphilis, Diarrhea in Infancy, and Psychiatry in the General Hospital and a symposium on Occupational Disease. Wednesday afternoon there will be panels on Diagnosis of Uterine Cancer, "Rooming In for Mothers and Infants," and symposiums on Treatment of Congenital Cardiovascular Anomalies and Thyrotoxicosis. Besides symposiums on Psychotherapy and Pulmonary Granulomas Thursday there will be panel discussions on Infectious Diseases, Liver Disease and Anemia.

IDAHO

Outbreak of Poliomyelitis.—Medical resources of Idaho have been mobilized to fight an outbreak of poliomyelitis which officials say has reached "epidemic proportions" in southwestern Idaho. By the middle of August 60 persons had been stricken this year as compared to 11 in the same period of 1946. The National Foundation for Infantile Paralysis Epidemic Aid Unit Team from Northwestern University Medical School, Chicago, comprising two doctors and three physical therapists, has been assisting.

ILLINOIS

State Hospital Plan Approved.—The state department of health has received notice that the Illinois hospital construction plan was approved by the surgeon general of the U. S. Public Health Service August 8. About $2,770,000 of federal funds is thus released for aiding the construction of local nonprofit hospitals in Illinois during the twelve months that began July 1. A similar amount will be available from the federal government for the same purposes during each of the next four succeeding years. The state has also appropriated $4,850,000 to aid in projects in line with the state plan. Based on the results of a hospital survey completed in 1946, the plan lists the areas according to the magnitude of the need for additional hospital facilities. Areas with no hospitals will have priority. Both federal and state funds will be administered by the state department of public health. A division of hospital construction and services has been organized under the direction of Dr. Henrietta M. Herbolsheimer, Chicago, for this purpose.

Chicago

Society Chooses Site for New Home.—Officials of the Chicago Medical Society and representatives of the Medical Center Commission signed an agreement August 20 for the purchase of 2½ acres of land between Damen and Ogden avenues facing on Congress street as the site for the new $2,000,000 home of the Chicago Medical Society, which it hopes to start building in 1950. In the five story building will be a lecture hall with a seating capacity of a thousand and special quarters for nineteen medical groups, a library, a museum of exhibits and office space.

Institute of Medicine Lecture Series.—The Institute of Medicine will present seven lectures by its fellows in its 1947-1948 series of "Where We Stand Today in Medicine." The meetings will be held on the second and fourth Friday afternoons of each month beginning September 12 from 4:45 to 5:30 in the assembly room of the institute. They will be open without fee to all physicians and allied professional groups. The program is as follows:

September 12, Roy R. Grinker, director, Institute for Psychosomatic and Psychiatric Research and Training, Michael Reese Hospital, Every Doctor a Psychiatrist.
September 26, Robert G. Bloch, professor of medicine, University of Chicago School of Medicine, Tuberculous Calcification: Clinical and Experimental Studies.
October 10, Herman L. Kretschmer, clinical professor of urology, University of Illinois College of Medicine, Present Status of the Prostatic Problem.
October 24, Stanley Gibson, professor of pediatrics, Northwestern University Medical School, Indications for Surgery in Congenital Cardiovascular Anomalies.
November 14, Paul W. Greeley, clinical associate professor of surgery, University of Illinois College of Medicine, Scope and Possibilities of Modern Plastic Surgery.
November 28, John R. Lindsay, professor of surgery, University of Chicago School of Medicine, Ménière's Disease: Diagnosis and Treatment.
December 12, Ralph E. Dolkart, associate in medicine, Northwestern University Medical School, Clinical Problems in the Use of Antibiotic Therapy.

LOUISIANA

Dr. Colomb to Head Department of Psychiatry.—Dr. Henry O. Colomb, New Orleans, has been appointed professor of psychiatry at Louisiana State University School of Medicine, New Orleans, and chief of the department of psychiatry. He will develop a program of undergraduate and graduate teaching at the medical school. He graduated at Tulane University of Louisiana School of Medicine in New Orleans in 1923, and was clinical director of the Connecticut State Hospital, Middletown, for a number of years and assistant superintendent at the Philadelphia General Hospital before setting up his private practice in New Orleans in 1942.

MICHIGAN

Dr. Ruedemann Appointed Head of Department.—Dr. Albert D. Ruedemann, Cleveland, for five years head of the department of ophthalmology, Cleveland Clinic Foundation Hospital, became head of the department of ophthalmology at Wayne University College of Medicine, Detroit, June 15. A graduate of the University of Michigan Medical School, Ann Arbor, 1921, he went to the Cleveland Clinic Foundation Hospital in 1924. Dr. Ruedemann received a gold medal from the American Medical Association for his exhibit of a permanent plastic eye at the San Francisco session of the Association in July 1946.

Expand Isabella County Health Program.—Isabella County, the city of Mount Pleasant and the Central Michigan College of Education are participating in the development of a program that will provide basic public services to all groups in the county. Emphasis will be placed on maternal and child health. The state and the federal government are supporting the program, and a large part of the financial support comes from funds allotted to Michigan by the Children's Bureau. Besides the director, Dr. Robert Hall, and his assistant there will be five public health nurses, a health educator, a sanitarian and two clerks on the staff. Attractive quarters have been made available in the Community Hospital, and Dr. Hall has been occupied with setting up committees that will play a large part in the development of the program.

MISSOURI

Kansas City Clinical Conference.—The twenty-fifth annual fall clinical conference of the Kansas City Southwest Clinical Society will be held in Kansas City October 6-9. The out of state speakers include:

William E. Adams, Chicago, Surgical Treatment of Carcinoma of the Esophagus.
Guy A. Caldwell, New Orleans, Diagnosis and Treatment of Low Back Pain Resulting from Trauma.
Roland S. Cron, Milwaukee, Endometriosis
Joseph S. D'Antoni, New Orleans, Chronic Diarrheas.
Robert Elman, St. Louis, Preoperative and Postoperative Use of Intravenous Fluids.
George H. Ewell, Madison, Wis., Anuria
Howard K. Gray, Rochester, Minn., Surgery of Malignant Lesions of the Stomach.
Russell L. Haden, Cleveland, Precipitating and Accelerating Factors in Arthritis.
John S. Lockwood, New York, Anticoagulants in Prevention and Treatment of Thrombosis and Embolism.
Douglas W. Macomber, Denver, Practical Suggestions in Early Treatment of Common Wounds.
Robert A. Moore, St. Louis, Nature of Endocarditis and the Effect of Penicillin in Healing.
Eugene P. Pendergrass, Philadelphia, How to Prevent Death from Breast Cancer.
Curtice Rosser, Dallas, Surgical Lesions of the Left Colon.
Leon Schiff, Cincinnati, Diagnosis of Gastric Cancer.
William D. Stroud, Philadelphia, Coronary Artery Disease.
Willard O. Thompson, Chicago, Uses and Misuses of Sex Hormones.

Exhibits, dinners and luncheons are included in the program. The $15 registration fee should be sent to the Kansas City Southwest Clinical Society, 630 Shukert Building, Kansas City 6.

NEW YORK

Arrange Lectures for County Societies.—The Medical Society of the State of New York and the New York State Department of Health have arranged two lectures of postgraduate instruction for the Tompkins County Medical Society. Dr. Lewis I. Sharp, New York, will speak on "The Recognition and Management of Psychosomatic Problems in General Practice" September 15 at the Tompkins County Memorial Hospital, Ithaca, at 8:30 p. m. On November 17 the society will hear Dr. Ralph R. Tompsett, New York, speak on "Antibiotics." For the Otsego County Medical Society a Teaching Evening has been arranged by the county and state societies to be held at the Elks Club in Oneonta September 10. Dr. Joe W. Howland, Rochester, will speak on "Medical Aspects of the Atomic Bomb" and Dr. Julius Redish Lynbrook, N. Y., on "Hypertension and Hypertensive Heart Disease."

Annual Academy Graduate Fortnight.—The Graduate Fortnight of the New York Academy of Medicine will be held October 6-17. The program includes morning panel discussions; afternoon clinics, evening lectures, scientific exhibits and demonstrations relating to disorders of metabolism and the endocrine glands. Out of state physician speakers for the evening lectures are:

Hans Selye, Montreal, Hypertension.
John S. L. Browne, Montreal, the Carpenter Lecture, Adaptation Syndrome in Man.
Louis H. Newburgh, Ann Arbor, Energy Metabolism in Obese Persons.
Abraham White, Ph.D., New Haven, Conn., Relations of the Adrenals to Immunity.
DeWitt Stetten Jr., Boston, Studies in Intermediary Metabolism Conducted with the Aid of Isotopic Tracers.
Daniel C. Darrow, New Haven, Conn., Disturbances in Electrolyte Metabolism in Man and Their Management.
William C. Rose, Urbana, Ill., Role of Amino Acids in Nutrition.
Nathan Shock, Baltimore, Metabolic Functions in Old Age.
Rulon W. Rawson, Boston, Hormonal and Chemical Factors Regulating Thyroid Function.
Edwin B. Astwood, Boston, Clinical Experiments with Antithyroid Compounds.
E. Perry McCullagh, Cleveland, Testicular Dysfunction, Some Clinical Aspects.
Carl G. Heller, Portland, Ore., Use of Androgens in Men.
Arthur T. Hertig, New Haven, Conn., Why Do Women Abort?
Joseph E. Markee, Ph.D., Durham, N. C., Morphological Basis for Menstrual Bleeding.

The registration fee is $5. Complete programs will be sent to nonmember physicians on request. Address Dr. Mahlon Ashford, 2 East 103d Street, New York 29.

New York City

Personals.—Dr. Oswald R. Jones, assistant clinical professor of medicine, Bellevue Hospital Columbia University College of Physicians and Surgeons, New York, has been appointed to a five year term as chairman of the state tuberculosis committee. ——Dr. Richard Kovacs has been elected an honorary member of the Royal Society of Medicine, Section of Physical Medicine, London.——Dr. Jacob M. Gershberg, New York, president of the International Spanish Speaking Association of Physicians, is on a trip to Mexico and Latin America to arrange a congress of Latin American physicians.

Research in Geriatrics.—The New York University College of Medicine and Memorial Hospital for the Treatment of Cancer and Allied Diseases, Welfare Island, will begin a project in research of old age diseases in September. The program will be carried out at the hospital by a staff of university research specialists under the supervision of Dr. J. Murray Steele, associate professor at the College of Medicine and director of the university's Third Medical Division at the hospital. Patients will be available for research over ten to fifteen years, which will make possible a continuous study of old age diseases as they affect the individual. The project calls for the study of a maximum of 10 patients at one time.

NORTH CAROLINA

Personals.—Dr. Charles W. Armstrong, Salisbury, was elected president of the Kiwanis International at the annual convention of the organization in Chicago in July. Dr. Armstrong, a graduate of the University College of Physicians and Surgeons, Baltimore, 1914, who has been health officer of Rowan County for nearly thirty years, was elected to the North Carolina State Board of Medical Examiners in 1944 and was president of the North Carolina Tuberculosis Association in 1941. He is now a director of the National Tuberculosis Association.——William A. Perlzweig, Ph.D., professor of biochemistry, Duke University School of Medicine, Durham, left August 17 to serve as a special adviser in the organization of the Hebrew University-Hadassah Medical School in Palestine.

OHIO

Research on Poliomyelitis.—Dr. Albert B. Sabin, professor of research pediatrics, University of Cincinnati College of Medicine, and attending pediatrician, Cincinnati Children's Research Hospital Foundation, will direct a $50,000 research program at the local foundation through funds supplied by the National Foundation for Infantile Paralysis, Inc., New York. The $50,000 grant will be used for study of the propagation of poliomyelitis viruses in mice of varying genetic constitutions and the immune response of patients to viruses recovered from their own alimentary tracts. He will investigate also whether the absence of epidemics of poliomyelitis in certain countries can be correlated with the development of immunity at an earlier age.

Admission of Mental Patients.—A new plan for handling patients who might be mentally disturbed has been put into action by the Probate Court and the Cincinnati General Hospital. The plan eliminates the necessity of such patients appearing in court under the impression that they have been accused of wrong doing. After examination by the psychiatrist of the Probate Court and of the General Hospital, the judge is left to decide whether the patient should be sent to Longview Hospital or be discharged. The plan was worked out by Judge Davies and Dr. Maurice Levine, with Dr. Milton Rosenbaum, professor of psychiatry and associate director of hospital psychiatric service, University of Cincinnati College of Medicine; Henry Hooper, superintendent, and Mrs. Elizabeth B. Trier, director of social service, all of General Hospital; Dr. Earl A. Baber, assistant professor of psychiatry, University of Cincinnati College of Medicine, and superintendent of Longview Hospital; Ed Penno, staff member; Dr. Douglas A. Johnston, Cincinnati, and Dr. James Robert Hawkins, psychiatrists.

TENNESSEE

Society News.—A Tennessee State Society of Pathologists was formed at the state medical meeting in Memphis in April by fourteen pathologists from various sections of the state. Dr. Alfred Golden, Memphis, was elected president; Dr. William A. De Monbreun, Nashville, vice president, and Dr. Thomas C. Moss, Memphis, secretary-treasurer.

Course in Anesthesiology and Obstetrics.—The postgraduate course in anesthesiology and obstetrics under the direction of Dr. Robert A. Hingson has been extended from a two week period to one month in order to give the matriculating physicians an opportunity to secure more clinical experience.

This course operated during 1943 and 1944 in the Philadelphia Lying-In Hospital. Since 1945 it has been conducted by the departments of obstetrics and gynecology and anesthesiology of the University of Tennessee College of Medicine at the John Gaston Hospital, Memphis. The next session begins September 15.

WASHINGTON

Health Officer of Spokane.—Dr. Jack B. Eason, Olympia, assumed duties as health officer of Spokane July 1. A graduate of Jefferson Medical College of Philadelphia, 1930, he has been health officer for the district including Thurston and Mason counties and the cities of Olympia and Shelton.

Classes for Spastic Children.—Special classes for spastic children will be set up soon in various parts of the state to help them by means of education, physical therapy and other aids. A series of screening clinics will be held to select the limited number who can benefit from the facilities offered. The state departments of public instruction and health have appointed an advisory committee. Plans are under way for expanding spastic classes now supported by several school systems as well as establishing new classes.

GENERAL

Obstetricians, Gynecologists and Abdominal Surgeons.—In the August 23 issue of The Journal, page 1498, the name of Dr. Clifford V. Ward, Montreal, was inadvertently omitted from the program of the annual meeting of this group. Dr. Ward spoke by invitation on "Blood Platelet Studies During Pregnancy and the Puerperium."

National Safety Congress.—The National Safety Congress and Exposition will be held in Chicago October 6-10. Sensitization Dermatoses, Primary Irritation Dermatoses and the Effect of New Industrial Chemicals on the Skin will be discussed October 8 at the Congress Hotel with Dr. Frederick W. Slobe, Chicago, presiding. Friday morning Dr. Ralph S. McLaughlin, Industrial Health Foundation, Charleston, W. Va., will speak on "Methods for Saving Eyes from Chemical Burns" at the Stevens Hotel at 9:45.

Dr. Telfer Named China Health Aid.—The World Health Organization has appointed Dr. James G. Telfer, Washington, D. C., as port health expert for China. He will help the Chinese ministry of health establish a training center for port and quarantine work. The staff selected by Dr. Telfer will first come to the United States for instruction. Dr. Telfer, on the staff of the U. S. Public Health Service for twelve years, served in the Hong Kong-Canton area in 1939-1940 and in the Philippines both before and after that time.

Tuberculosis Society Elections.—At the recent meeting of the National Tuberculosis Association in San Francisco the following officers were elected: Dr. James R. Reuling, Bayside, N. Y., president; Dr. Herbert L. Mantz, Kansas City, Mo., president-elect, and Dr. H. Stuart Willis, Sanatorium, N. C., secretary.——The National Trudeau Society elected Dr. Howard W. Bosworth, Los Angeles, president; Dr. H. Corwin Hinshaw, Rochester, Minn., president-elect, and Dr. David A. Cooper, Philadelphia, secretary-treasurer.——The National Conference of Tuberculosis Secretaries has elected Mr. Donald E. Pratt, St. Louis, president.

Impostor Solicits Accounts of Deceased Physician.—Notice has been received of a man, posing as a representative of the American Medical Association, calling on a doctor's widow for the purpose of soliciting accounts left by her husband. The heading on his listing sheet is A. M. A., Department of Estates, Offices at Hill City, South Dakota, P. O. box 265. The American Medical Association employs no such individual nor has it any association with an individual empowered to solicit accounts in this fashion. Furthermore, the Association would appreciate any information concerning this man or any other of his kind so that whatever action is indicated can be taken.

Special Society Elections.—The American Federation for Clinical Research has elected as officers for the coming year Drs. Paul M. Aggeler, San Francisco, president; John S. La Due, New York, secretary; Charles H. Rammelkamp, Cleveland, treasurer. Meetings of the organization for this year are: Far Western Section at the San Francisco County Medical Building, San Francisco, November 6; Midwestern Section at the Knickerbocker Hotel, Chicago, October 30; Eastern Section at Cornell University Medical College, New York, December 12, and Southern Section at the Roosevelt Hotel, New Orleans, January 30; national meeting, Atlantic City, May 4, 1948.

Prevalence of Poliomyelitis.—Reports of cases of poliomyelitis for the periods indicated have been received from the division of public health methods, U. S. Public Health Service:

CORRECTION

Eosinophilic Granuloma of Bone.—The author of the communication entitled "Eosinophilic Granuloma of Bone" in The Journal, August 16, page 1437, desires that the words "to the paper" be inserted in the eleventh line after the word "made."

Marriages

Zenas W. Ford Jr., Fayetteville, Ark., to Miss Virginia Fern Marsh in Ancon, Canal Zone, April 8.

Ward L. Oliver, Cobleskill, N. Y., to Miss Virginia M. Loucks of Gloversville April 8.

John T. Branciforte, Bondsville, Mass., to Miss Helena E. Wilga of Ware April 13.

Paul M. Brenner, Quincy, Ill., to Miss Elizabeth Brasfield of Hickman, Ky., May 3.

Deaths

Elliott Carr Cutler ✠ Moseley professor of surgery at Harvard Medical School and at the graduate school in Boston, died at his home in Brookline, Mass., August 16, aged 59, of carcinoma of the prostate. Dr. Cutler was born in Bangor, Maine, in 1888, and graduated from Harvard Medical School in 1913. At the outbreak of World War I he was placed in charge of the first Harvard medical unit in Paris, receiving a captain's commission in May 1917 and a promotion to major when placed in charge of Base Hospital number 5. Returning to civilian life in 1919, he became an instructor in surgery at Harvard and in 1921 was named chairman of the department of surgery and the laboratory of surgery. He served as professor of surgery at Western Reserve University School of Medicine and director of surgery at Lakeside Hospital, Cleveland, from 1924 to 1932, when he succeeded the late Dr Harvey Cushing as Moseley professor of surgery at Harvard and chief surgeon at the Peter Bent Brigham Hospital.

During the early part of World War II he was head of the medical aid division of the Massachusetts Committee on Public Safety. In 1942 he became colonel in the medical corps, Army of the United States, and later was promoted to brigadier general. He served with distinction as chief consultant in surgery and as chief of professional services in the European Theater of Operations and in 1945 was appointed consultant to the Veterans Administration. He was awarded the Legion of Merit, the Distinguished Service Medal with Oak Leaf Cluster, the Order of the Empire by King George VI of Great Britain, the Croix de Guerre by the French government, Companion of the Order of the Bath, and Chevalier of the Legion of Honor. At the time of his death Dr. Cutler was consultant to the surgeon general of the army and a member of the special medical advisory committee to the Secretary of War. He was a founder of the American Board of Surgery, a member of the American Surgical Association, Society of Clinical Surgery, New England Surgical Society, American Heart Association, American Association for Thoracic Surgery, American Society for Clinical Investigation, Society of Experimental Biology and Medicine, American Society for Experimental Pathology and the Association of Military Surgeons of the United States. Dr. Cutler was a member of the Committee for the Protection of Medical Research of the American Medical Association. In 1927 he was elected a member of the Royal Academy of Medicine of Rome, an honorary fellow of the Royal College of Surgeons of England and was a member of other scientific societies in this country and abroad He was a fellow of the American College of Surgeons. An honorary degree was conferred on Dr. Cutler by the University of Strasbourg, France, in 1938 and by the University of Rochester, Rochester, N. Y., in 1946. He was the author with Dr. Robert Zollinger of "Atlas of Surgical Operations," an associate editor of the *American Journal of Surgery* and a member of the editorial board of the *British Journal of Surgery*. He was a member of the board of overseers of Harvard University from 1927 to 1932 and president of the Associated Harvard Clubs, 1936-1937. Among his numerous other publications was an extensive article in the *Archives of Surgery* in 1924 on the Surgical Treatment of Mitral Stenosis in which he reported what was said to be the first successful operation on the valves of the human heart.

Hibbert Winslow Hill, Hackensack, Minn.; born in St. John, N. B., Sept. 16, 1871; M. B., University of Toronto Faculty of Medicine in 1893, with a postgraduate scholarship; appointed demonstrator in pathology and bacteriology and in charge of the clinical laboratory of the Toronto General Hospital; in 1895 took a postgraduate course in bacteriology at the Johns Hopkins Hospital; during the following years served as director of the bureau of laboratories for the Brooklyn health department and of the Boston board of health; in 1899 received the Starr Gold Medal with an M.D. from Toronto University; during his residence in Boston was extramural instructor in bacteriology at Harvard Medical School; for many years assistant director of the laboratories and epidemiologist for the Minnesota State Board of Health and assistant professor of bacteriology at the University of Minnesota; served as director of the Institute of Public Health in the University of Western Ontario, London, where he was professor of public health and medical officer of health of the city of London; for many years executive secretary of the Minnesota Public Health Association; during World War I served on the headquarters staff of the First Military District of Canada; later appointed director of laboratories of the Vancouver General Hospital and professor of bacteriology and of nursing and health in the University of British Columbia; served as chairman of the laboratory section of the American Public Health Association and as a member of various committees of that section; at one time editor of the *Minnesota Public Health Journal;* author of the "New Public Health", "Sanitation for Public Health Nurses," "New Hygiene" and contributed to other volumes; one of the founders of the Boston Bacteriological Club; member of many medical and scientific societies; in 1930 received the honorary degree of LL.D. from the University of Western Ontario; died May 23, aged 75, of complications from a spinal cord lesion.

Thomas Henshaw Kelly ✠ San Francisco; born in Covington, Ky., Jan. 5, 1890; Medical Department of the University of Cincinnati, 1914; associate clinical professor of obstetrics and gynecology at the Stanford University School of Medicine, where he had been acting chairman of the department, 1944-1945; past president and secretary of the San Francisco County Medical Society; past president of the San Francisco Gynecological Society; member of the House of Delegates of the American Medical Association in 1935; secretary of the National Federation of Obstetrical and Gynecological Societies; fellow of the Pacific Coast Society of Obstetrics and Gynecology; member of the council from 1929 to 1938 and chairman of the council from 1933 to 1936, California Medical Association; trustee from 1939 to 1945, chairman of the executive committee, assistant secretary and later assistant treasurer of the California Physicians' Service from 1939 to 1944; served during World War I; chief of the obstetric service, Mount Zion Hospital; on the staff of St. Francis Hospital; founded and was first editor of the *Bulletin of the San Francisco County Medical Society;* died May 10, aged 57, of coronary occlusion.

George Wade Wilson, Venice, Calif.; born in St. Louis in 1891; St. Louis University School of Medicine, 1914; assistant in medicine and pathology from 1915 to 1917 and since 1924 associate professor of medicine at his alma mater; assistant in pathology and bacteriology at the Rockefeller Institute for Medical Research in New York from 1917 to 1919; professor and head of the departments of pathology, bacteriology and preventive medicine at the Loyola University School of Medicine in Chicago, 1919-1920, and associate in medicine at the Washington University School of Medicine in St. Louis from 1920 to 1924; at one time associate professor of clinical medicine at the University of Southern California School of Medicine in Los Angeles; served on the staffs of St. Vincent's Hospital in Los Angeles, Mercy Hospital in Chicago and Jewish, Barnes and Missouri Pacific hospitals in St. Louis; formerly consultant to the New York Central Railroad; shot and killed by a patient June 6, aged 55.

Walter Hobert Watterson ✠ La Grange, Ill.; born in Fairbury, Ill., Feb. 12, 1875; Northwestern University Medical School, Chicago, 1901; member of the American College of Chest Physicians; member and past president of the Chicago Tuberculosis Society; fellow of the American College of Physicians; served during World War I; affiliated with the Zace Sanitarium in Winfield and the West Lake Hospital in Melrose Park; formerly on the staff of the Veterans Administration Facility in Hines, Ill., superintendent of the Chicago Municipal Tuberculosis Sanitarium, Lake Breeze Sanitarium in Waukegan, Ill., and the Pokegama Sanitarium in Pokegama, Minn.; at one time affiliated with the Cook County Tuberculosis Hospital in Oak Forest, Ill.; formerly instructor in tuberculosis for the U. S. Public Health Service; died June 17, aged 72, of heart disease.

Edward L. Hanes ✠ Rochester, N. Y.; born in Chenango Forks, N. Y., Jan. 2, 1871; Albany Medical College, 1899; past president of the Rochester Academy of Medicine; member of the Rochester Pathological Society and the American Psychiatric Association; fellow of the American College of Physicians; during World War I in charge of the neuropsychiatric division of base hospital number 19, serving overseas; later served as consultant in neuropsychiatry for the Veterans Administration; served on the staffs of the Craig Colony in Sonyea, Hudson River State Hospital at Poughkeepsie, Rochester State Hospital, Rochester General Hospital, St. Mary's Hospital and the Genesee Hospital; author of "Minds and Nerves of Soldiers"; died in Altadena, Calif., June 14, aged 76, of coronary disease.

of hypertensive heart dis

Otis Johnson Baldwin, Chicago; St. Louis University School of Medicine, 1903; member of the American Medical Association; affiliated with the West Suburban Hospital in Oak Park and St. Ann's Hospital; formerly on the staffs of the Chicago and the Kankakee (Ill.) state hospitals; died June 25, aged 79, of gastric ulcer and heart disease.

Malcolm Campbell ⊕ New York; Medical College of Virginia, Richmond, 1901; professor of gynecology and obstetrics at the New York Polyclinic Medical School and Hospital; fellow of the American College of Surgeons; served during World War I; on the staff of St. Clare's Hospital; died June 1, aged 71, of coronary thrombosis.

Charles Broadway Danruther, La Porte, Ind.; Indiana University School of Medicine, Indianapolis, 1914; member of the American Medical Association; served as city health officer and as county coroner; died in the Holy Family Hospital June 16, aged 55.

Arthur Lardovic Duplantis, Chicago; Chicago College of Medicine and Surgery, 1913; member of the American Medical Association; died June 29, aged 65, of coronary thrombosis.

Robert Lee Edwards, Salem, Ore.; University of Oregon Medical School, Portland, 1914; member of the American Medical Association; died June 7, aged 67, as the result of injuries received in an automobile accident in August 1946.

Floyd Lester Gilles ⊕ Minneapolis; Syracuse University College of Medicine, 1917; served during World War I; on the staffs of the Asbury Hospital and Fairview Hospital; died recently, aged 55, of heart disease.

William H. Goodrich ⊕ Augusta, Ga.; University of Georgia Medical Department, Augusta, 1897; emeritus professor of clinical gynecology at his alma mater, where he formerly served as dean; formerly medical superintendent of the University Hospital; accidentally drowned recently while fishing in Port Royal Sound, S. C., aged 73.

Adam Mader Hauer ⊕ Lebanon, Pa.; Johns Hopkins University School of Medicine, Baltimore, 1939; diplomate of the National Board of Medical Examiners; interned at the Lancaster General Hospital in Lancaster; served overseas in the medical corps, Army of the United States, during World War II; city school physician; associate surgeon, Good Samaritan Hospital; drowned May 11, aged 33, when his boat was swept over the Holtwood Dam on the Susquehanna River while fishing.

Maude Noble Haven, San Francisco; Cooper Medical College, San Francisco, 1900; formerly on the staff of the Stanford University Hospital where she died May 28, aged 74.

Peter Matthias Holl, Minneapolis; Minnesota Hospital College, Minneapolis, 1887; Bellevue Hospital Medical College, 1888; served as city physician; member of the American Medical Association; died in the Northwestern Hospital recently, aged 84, of arteriosclerotic heart disease and encephalopathy.

John Conrad Holzberger ⊕ Brooklyn; Long Island College Hospital, Brooklyn, 1915; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; served during World War I; on the staffs of the Brooklyn Eye and Ear, Bethany Deaconess and Wyckoff Heights hospitals; died May 31, aged 54.

Ben Hudson, Springfield, Ill.; St. Louis Medical College, 1885; died in St. Louis May 15, aged 86, of a fractured hip received in a fall.

Sam Jaeggli, Moulton, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1920; member of the American Medical Association; served in the Texas National Guard on the Mexican border and during World War I; died recently, aged 55, of coronary thrombosis.

Galvin Luther Johnson ⊕ Pauls Valley, Okla.; Memphis (Tenn.) Hospital Medical College, 1903; served as vice president of the Oklahoma State Medical Association and as a member of the state board of medical examiners; affiliated with the Lindsey-Johnson-Shirley Hospital; died May 11, aged 67, of heart disease.

Ellis Adrian Johnston, Seattle; Northwestern University Medical School, Chicago, 1904; served in the medical corps of the U. S. Army as a captain and with the American Expeditionary Forces during World War I; formerly health officer of Helena, Mont., where he served as coroner of Lewis and Clark County; died suddenly June 4, aged 70, of coronary thrombosis.

Sherman J. Jones, Hastings, Neb.; College of Physicians and Surgeons, Keokuk, Iowa, 1891; Rush Medical College, Chicago, 1898; member of the American Medical Association; on the staff of the Mary Lanning Memorial Hospital; died May 26, aged 86, of arteriosclerosis.

Edward Philip Kennedy, Swaledale, Iowa; State University of Iowa College of Medicine, Iowa City, 1912; member of the American Medical Association; health officer; on the staff of St. Joseph's Mercy Hospital in Mason City, where he died May 27, aged 65, of coronary occlusion.

Solomon S. Kerr, Lincoln, Ill.; Chicago College of Medicine and Surgery, 1917; affiliated with the Lincoln State School and Colony; died May 20, aged 66.

Elmer Christian Kieffer, Reading, Pa.; Medico-Chirurgical College of Philadelphia, 1899; died recently, aged 73.

Joe Hilliard Kirby Jr., Loris, S. C.; Tulane University of Louisiana School of Medicine, New Orleans, 1942; interned at the Medical College of Virginia, Hospital Division, Richmond; member of the American Medical Association; served in the medical corps, Army of the United States, during World War II; died in New Orleans May 16, aged 29, of acute leukemia.

Casimir Boleslaus Kitowski ⊕ San Antonio, Texas; University of Texas School of Medicine, Galveston, 1915; served during World War I; examining physician for the Selective Service system in Bexar County during World War II; member of the staffs of the Nix, Physicians and Surgeons and Medical and Surgical Memorial hospitals; died recently, aged 58, of cerebral hemorrhage.

Wilhelm Edmund Harmon Krechting ⊕ Washington, D. C.; Johns Hopkins University School of Medicine, Baltimore, 1906; died May 27, aged 69, of cerebral hemorrhage.

Thomas Downs Laftry, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1899; member of the American Medical Association; medical director of the Great Northern Life Insurance Company; for many years affiliated with the Norwegian-American Hospital, where he died May 23, aged 79, of agranulocytosis.

Louis A. Larson, Kane, Pa.; Jefferson Medical College of Philadelphia, 1896; died June 5, aged 75, of coronary thrombosis.

Julian Dyer Lucas, Brookline, Mass.; Tufts College Medical School, Boston, 1902; served during World War I; died June 3, aged 69.

Earl Lane Lupton, Sebastopol, Calif.; College of Physicians and Surgeons, Los Angeles, 1917; served during World War I and as public health director in Los Angeles city and county; died June 5, aged 52, of gastric hemorrhage.

Fred Houston Mecom ⊕ Columbia, La.; Memphis (Tenn.) Hospital Medical College, 1907; served during the Spanish-American War; died June 3, aged 69, of cerebral hemorrhage.

George Alfred Plummer ⊕ Rochester, N. Y.; Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1902; member of the Iowa State Medical Society; past president of the Howard (Iowa) County Medical Society; fellow of the American College of Surgeons; served during World War I; formerly president of the board of education of Cresco, Iowa, where he was health officer and on the staff of St. Joseph Mercy Hospital; died May 23, aged 68.

Lilburn Woods Renfro ⊕ Seattle; Rush Medical College Chicago, 1913; served during World War I; died May 3, aged 70, of coronary thrombosis.

Nicholas Aloys Schneider ⊕ St. Louis; St. Louis University School of Medicine, 1921; formerly on the faculty of his alma mater; on the staffs of the Alexian Brothers Hospital and St. Anthony's Hospital, where he died May 3, aged 50, of hemorrhage of the spleen.

Stephen Herbert Smith ⊕ Pasadena, Calif.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1905; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; medical director of the Las Encinas Sanitarium; died June 3, aged 66, of coronary thrombosis.

Ernest Brent Thompson, El Paso, Texas; Vanderbilt University School of Medicine, Nashville, 1914; member of the American Medical Association; served during World War I; died recently, aged 58, of diabetes mellitus and acute appendicitis.

Frank Warren White, Rockwood, Pa.; Tufts College Medical School, Boston, 1907; member of the American Medical Association; died recently, aged 66, of congestive heart disease.

Martha Alice Wood ⊕ Houston, Texas; University of Texas School of Medicine, Galveston, 1903; member of the South Texas District Medical Society, Texas Society of Pathologists and the American Society of Clinical Pathologists; for many years director of the clinical laboratory and of pathology at the Methodist Hospital; died recently, aged 69, of coronary occlusion.

Medical Cooperation with the Dominions

At a meeting of the council of the British Medical Association the president, Sir Hugh Lett, introduced the report of a special committee which had been considering means for securing closer liaison with the British dominions in matters affecting the common interests of practitioners in them and in Britain. The need for this had been strongly felt by the committee, which proposed that the Canadian Medical Association, the Federal Council of the Association in Australia, the New Zealand branch of the association, the South African Medical Association, the Medical Association of Eire, the Newfoundland Medical Association and the branches of the association in southern Rhodesia be invited to cooperate with the council in London in establishing a "British Commonwealth Medical Council" for the purpose of developing closer contact between practitioners in Britain and in the various dominions, for advancing the status of British medicine, for the discussion and exchange of views on matters of common interest and for promoting an exchange of professional facilities. Each member association would appoint three representatives on the Commonwealth Council, which would meet at least once a year, first in London in 1948.

Arising out of this was the important point of men who came to London for postgraduate work and in some cases for undergraduate work. A number of bodies were interested in these people, but there was no communication among them and there was a certain amount of overlapping. The committee felt that when a medical man came to London on a visit from the dominions he should be advised to go straight to the British Medical Association, where he would be given information and help in various directions on both the academic and social sides. It was not merely a matter of formal arrangements for study but of a personal welcome. It was therefore further proposed that the principle of establishing an Empire Medical Advisory Bureau at the British Medical Association House to assist practitioners, particularly those from the dominions and colonies, visiting Britain, be approved, and that the secretary be instructed to draw up a detailed plan for the consideration of the council. The proposal was adopted.

Penicillin Treatment of Osteomyelitis in Childhood

The striking improvement in the results of treatment of staphylococcic osteomyelitis of children due to penicillin is well known. But the results in a series of unselected cases at the National Hospital for Sick Children, Great Ormond Street, mark an advance by showing the extent to which operation for removal of the affected bone can be discarded. They were recorded in the *British Medical Journal* May 31 by T. Twistington Higgins, Denis Browne and Martin Bodian. The details of treatment are important since there is no agreement as to the dosage of penicillin or as to the surgical intervention which may be necessary in addition. In 31 consecutive cases of acute osteomyelitis 16 occurred under 1 year of age, the others ranging up to 12 years. The lesions were in the long bones in 23 cases, other sites being the external cuneiform, frontal bone, sternum and maxilla. In 4 the infection had spread to a neighboring joint. Soft tissue abscesses occurred in 12 cases and septicemia in 3. The duration of the disease before admission was less than one week in 19, up to four weeks in 8, and up to eight weeks in 3. Staphylococcus aureus was grown from the blood stream in 2 cases and from abscesses or joints in 12.

Penicillin treatment was begun at once without waiting for the bacteriologic report. The dosage was 1,000 units every twenty-four hours per pound of body weight given by intramuscular injection at intervals of four hours. It was considered safest to continue this treatment for at least three weeks. In the surgical treatment the limb was immobilized in plaster so that inspection of the affected region and aspiration could be performed easily. Immobilization was not prolonged much beyond the period of penicillin treatment. The treatment differed from that generally followed in 13 cases in which pus formed outside the infected bone. In all these the pus was aspirated at intervals depending on the rate of reformation—in most cases daily for the first few days, then at longer intervals. The pus was always replaced by injecting penicillin in a dose of 2,000 to 5,000 units.

In all cases, to the authors' surprise, pus finally ceased to form and healing was complete without sinus formation. The advantage of this conservative treatment was that it avoided the disastrous change in outlook which occurs when the single penicillin controllable infection becomes complicated by nonsensitive organisms. The immediate clinical results were striking. Children admitted in great pain with high temperatures were happy again within forty-eight hours. Soft tissue swellings without formation of pus usually subsided in four or five days. Functional results were perfect in all cases but 1.

There was another series of 4 cases of acute suppurative arthritis. These were treated with aspiration and penicillin replacement. Finally there were 5 cases of chronic osteomyelitis: 3 of the rib, 1 of the os calcis, and 1 of the ilium. The affected bone was completely removed. All granulations were carefully scraped away, and penicillin in solution or in powder was instilled. The wound was then sewn up to avoid contamination by penicillin resisting organisms, and firm pressure was applied by elastoplast. Healing took place in all. It is important to note that this treatment is applicable only to cases in which all infected bony and soft tissue can be removed. Cases in which this is not possible, as in the upper end of the femur or in the vertebrae, still remain intractable once a communication has been formed with the surface of the body.

The British Journal of Cancer

Though research on cancer has been active for many years and the Imperial Cancer Research Fund was founded forty-four years ago under the direction of the Royal College of Physicians and Surgeons, it is only now that a journal devoted wholly to cancer has appeared. This quarterly, called the *British Journal of Cancer,* is the official organ of the British Empire Cancer Campaign. The need for a specialized journal became acute during the war years. The synthesis by Kennaway and Cook of the carcinogenic chemicals ten years ago has stimulated research in this and other countries. Discoveries followed in America on pure line breeding and hybridization of mice with a high incidence of mammary cancer, and Bittner's revelation of the tumor agent in the milk of mice. An outlet for the large volume of work had to be found in the two British journals devoted to pathology and bacteriology, the American journals of cancer research and other channels. Because of the lack of special journals, the papers on cancer were widely scattered. According to Professor Kennaway they were dispersed in some sixty journals and annual publications.

The first number is profusely illustrated. In the article on "Invasion of the Internal Mammary Lymph Glands in Carcinoma of the Breast," from the Bland Sutton Institute of Pathology of the Middlesex Hospital, R. S. Handley and A. C. Thackray report that in 4 out of 5 [illegible] cases of cancer of the breast a lymph gland of [illegible] mammary chain, removed through an incision in [illegible] or shortly after operation, was proved histologically to contain carcinoma, though in only 2 cases were there axillary deposits. They suggest that the technic of radical mastectomy should be modified to include removal of the second space internal mammary lymph gland. That might assist the prognosis and the postoperative treatment with radiation. Another article is "Abnormal Mitosis in Tumors," by P. C. Koller and "Induction of an Experimental Tumor of the Lens," by Ida Mann. The author has shown that a tumor can be induced by chemical carcinogens, although the lens is an organ in which tumors never occur naturally. The publishers of the *British Journal of Cancer* are Messrs. H. K. Lewis & Co., Ltd., 136 Gower Street, London W. C. 1. The annual subscription is $8.40.

The Frequency of Cirrhosis of the Liver

Half a century ago, cirrhosis of the liver was quite common and was traced to overindulgence in alcohol. Now it has become quite uncommon, and we have become diffident about its genesis and relationship to alcohol. At the hospital De Gamles By, Dr. J. Bock of Copenhagen has scrutinized the findings of 3,177 postmortem examinations conducted in the period 1939-1946. He succeeded in finding 137 cases (4.3 per cent) in which, with only one exception, Laënnec's cirrhosis of the liver was found. As none of the patients in this hospital were under the age of 61, the aforementioned percentage must not be taken as a mirror of the population of Denmark as a whole, but it does show that we have not completely rid ourselves of this disease and that its sex incidence seems to have changed of late. A few years ago, males were supposed to be more prone to this disease than females; but in the present study there were only 47 males to 90 females. In only 5.8 per cent was there a history of chronic alcoholism, and the correct diagnosis was made during life in only 11 cases. Abandoning the cocksure attitude of a past generation, Dr. Bock admits that we must now look for a new factor to explain the present tendency of cirrhosis of the liver to attack elderly women.

Sinusitis in Children

At the Finsen Institute in Copenhagen there is a special "ambulatorium" to which children are sent for light treatment. The head of this department, Dr. Eigil Rekling, and the head of the radiologic department of the Finsen Institute, Dr. Börge Worning, since 1937 have paid special attention to the part played by sinusitis in the chronic, catarrhal conditions of the upper respiratory tract of children. Their recent communication on the subject, published in the June 20 issue of *Nordisk medicin*, covers the year 1938, when 683 children were referred to the "ambulatorium" for diagnosis and treatment. Five hundred of these children between the ages of 3 and 15 were subjected to a systematic examination of the upper respiratory tract with special reference to x-ray findings. Many of them suffered from mucopurulent rhinitis, cough and various conditions commonly associated with tonsillitis and adenoids.

The examiners were surprised to find an impressive proportion of these children, 41 per cent of the boys and 38 per cent of the girls, suffering from sinusitis. By the inclusion of children presenting no signs of sinusitis, this investigation was provided with controls. The maxillary sinus was most often involved, the frontal sinus seldom, and only when the ethmoid sinus was also diseased. The maxillary sinus was never painful or tender, and many of these cases would have been overlooked and labeled as "tonsils and adenoids" but for the telltale evidence of the x-ray examination.

Is Appendicitis a Seasonal Disease?

A generation ago the Nestor of abdominal surgery in Denmark, Professor Rovsing, taught that appendicitis is comparatively frequent in September on account of overindulgence in fruit, and at Christmas time on account of a whole hearted devotion to Christmas fare. He passed these impressions on to his colleagues with the forceful emphasis which made him in many quarters a popular teacher. But were his deductions sound? Hardly, to judge by a study recently undertaken by Dr. Franz Sörensen, who has calculated the monthly incidence of appendicitis dealt with at a hospital in Aalborg in the twenty-five year period January 1922-January 1947. In 2,076 cases the diagnosis of appendicitis was confirmed by operation. His tabulation of cases according to the months in which they began shows a peak of 207 in July and a minimum of 144 in December. Between these two extremes (which in themselves are not very far apart) the cases were distributed among the remaining ten months with remarkable impartiality. More interesting than this refutation of an old fallacy is the disquieting and humiliating observation that 26 per cent of all these patients belonged to the second and third stages of appendicitis, with evidence of peritonitis.

Claims by Patients for Compensation

Recent communications in the medical press show how dangerous the practice of medicine has become for the doctor himself. The problem is largely one of loyalties. A generation or two ago relations between patient and family doctor were so personal and amicable that claims for compensation for mistakes were almost unthinkable. Even now doctors are seldom called to account for their diagnostic mistakes. Perhaps the public does not realize the tremendous importance of a correct diagnosis. In an analysis of 220 claims by patients for damages, Dr. Hans Heckscher has shown that in 36 cases an injection through the skin led to trouble for the doctor; in 10 cases an injection into the forearm was claimed to have led to "paralyses and invalidism" requiring the soothing balm of pecuniary compensation. An eminent jurist, Dagfinn Dahl, has suggested that claims for compensation have become numerous largely because money is now available for meeting such claims out of the pockets of impersonal insurance societies. So we have this curious situation: To protect himself a doctor subscribes to an insurance society and in so doing is asking for trouble. Not that he can avoid it, now that the public has acquired the habit of mulcting insurance societies for the alleged mistakes of doctors. However true the dictum "Insurance breeds claims," we cannot break loose from this vicious circle. In 1941 the Danish Medical Association created a committee to act in an advisory capacity with regard to alleged doctors' mistakes, and now the doctor who makes them, or is accused of making them, has no excuse for the unpardonable folly of dealing directly with the patient and his lawyer.

The Parking of Doctors' Cars

The other day a doctor got into trouble with the police in Copenhagen over the untimely parking of his car. It was quite a trifling incident but it led to a heart to heart talk between the representatives of the two professions, both indispensable to the public and both endowed with the priceless gift of a taste for compromise. The doctors said, in effect, "We do so fully appreciate your sense of law and order," to which the police replied with a friendly bow "We do so appreciate your difficulties when you give your medical services to the public, ourselves included." So it was arranged that some latitude should be shown to doctors over parking rules, provided they were not flagrantly ignored. And the doctors of Copenhagen are put on their honor not to abuse the benevolent inattention of the custodians of the law.

ITALY

Florence, June 30, 1947.

Epidemiology and Prophylaxis of Typhoid

Professor G. Mazzetti, director, Hygienic Institute, University of Florence, presented to the medical academy in Pistoia a report on the prophylaxis and epidemiology of typhoid. He spoke briefly on the significance of some epidemics which occurred recently in Prato and in Florence. The epidemiology of typhoid still lacks an explanation for several problems, especially those of epidemics originating in water supplies which cannot be confirmed by bacteriologic investigations.

Professor Mazzetti reviewed the laboratory methods which aid in diagnosis. He emphasized the significance of the antibodies O, H and Vi. The antibodies O are of specific significance in serologic differentiation between patients with typhoid and persons immunized against typhoid-paratyphoid, since in typhoid they appear early and disappear more rapidly than the H antibodies, while in vaccinated persons they do not appear at all or only temporarily, so that the observation of O antibodies in the patient and especially the determination of their increase during the disease can be considered as a definite criterion in the diagnosis of typhoid fever. The search for Vi antibodies is of special importance for tracing carriers of typhoid. Recent papers of foreign authors confirm these observations. This technic is the only means of studying the spread of epidemics of typhoid, by finding the source of the contagion.

Professor Mazzetti recalled the methods of prophylaxis of typhoid, including the vaccines administered by either the subcutaneous or the oral route; he insisted on the usefulness of extending immunization by the oral route.

Technic for Descending Pyelography

Drs. Conzi and Zaccone presented to the Medical Academy of Genoa a report on a new method for carrying out descending pyelography. They pointed out the difficulties that may be encountered in the interpretation of the roentgenograms when normal technics of descending pyelography are used. They recalled the artifices with which experiments have been made for blocking the evacuation of the ureter They had achieved such a blockage by means of a small balloon introduced into the bladder by means of a semirigid catheter. By this means the speakers have achieved a complete and perfect injection of all the superior urinary passages from the smallest details of the calices to the retrovesical portion of the ureter, visible through the air contained in the balloon The pressure is from 40 to 80 mm. of mercury. The use of this method is no more difficult than when using a common catheter; its advantages were demonstrated by roentgenograms presented by the speakers.

BRAZIL

(From Our Regular Correspondent)

Rio de Janeiro, July 15, 1947.

Duration of Life After Coronary Thrombosis

Dr. Jairo Ramos, professor of medicine at the Paulista Medical School of São Paulo, published a study of 100 patients who had been stricken with acute coronary thrombosis. The age of 1 patient at the moment of the attack was 35 years, of 36 patients from 36 to 50, of 41 patients from 51 to 60, of 17 patients from 61 to 70 and of 5 patients 71 and more years. At the moment of the attack the average age of the male patients was 50 years and that of the female patients 64 years. Of the 100 patients 28 died, 4 immediately after the attack, 7 a few months later, 13 between one and three years later and 4 between four and eight years after the attack. Of 72 patients alive at the moment of the study, 39 were living from a few months up to three years, 20 between four and five years and 13 from six to fourteen years. The study of the clinical picture of these patients disclosed six types: 20 patients did not present any symptoms after the attack; 18 patients complained only of pain; 9 patients presented only effort dyspnea; 18 patients presented pains and effort dyspnea; 31 patients presented continuous cardiac failure; 4 patients died from the first attack. Hypertension was present and aggravated the condition in 31 per cent of the patients. The number of patients who died from a second attack was five times as large as the number of those who died from the first. Dr. Ramos's conclusions are that advanced age, cardiac failure, hypertension and a new attack were the most important factors in the duration of life after the first attack.

Tyrothricin as a Means of Purifying Antivariolic Vaccine

After encouraging results obtained by the use of penicillin for the purification of antivariolic vaccine, Dr. Cassio Miranda, head of the Virus Division of the Oswaldo Cruz Institute, Rio de Janeiro, decided to try tyrothricin for a similar purpose. He used tyrothricin (Parke-Davis, for research work) dissolved in a 1 per cent concentration in 95 degree alcohol, this solution diluted in glycerin 1:9, or a final concentration of 1/1,000 of tyrothricin. The glycerinated vaccine pulp was then mixed with the tyrothricin solution in variable proportions: sample 1 had 4 cc. of pulp to 1 cc. of tyrothricin solution, sample 2 had 3 cc. of pulp to 1 cc. of the drug, sample 3 had 2 to 1 and sample 4 had 1 to 1. Sample 5 was glycerinated vaccine pulp without tyrothricin.

For the determination of tyrothricin's action on the associated bacterial flora of the vaccine, amounts of 0.05 cc., 0.1 cc., and 0.2 cc. of samples 1, 2, 3 and 4 were added to 15 cc. of nutrient agar melted at 45 C. in twelve separate incubation plates. Three more plates respectively received 0.05, 0.1 and 0.2 cc. of vaccine pulp without tyrothricin, and all the fifteen plates were incubated at 37 C. for forty-eight hours. Examination of the colonies showed a progressive decrease of the bacterial flora in the different samples of pulp (1, 2, 3 and 4) containing tyrothricin, while in sample 5 (vaccine pulp without tyrothricin) the number of colonies was not reduced. In samples 1 and 2, in spite of the reduction of germs, the number of colonies was still practically incalculable. But in sample 3 (2 parts of glycerinated pulp to 1 part of tyrothricin solution) the plate with 0.2 cc. showed only 1,076 colonies, and in sample 4 (1 part of pulp to 1 part of solution) the plate with 0.2 cc. showed only 49 colonies. Skin inoculation in rabbits demonstrated in all the samples the perfect resistance of the vaccine virus to tyrothricin. The vaccine virus resisted during eighty-five days the antibiotic action, giving positive reactions even in the dilution of 1:1,000.

Tuberculosis of the Female Genitalia

Dr. Arnaldo de Moraes, professor of clinical gynecology at the University of Rio de Janeiro, presented 8 cases of tuberculosis of the female genitalia registered among the last thousand consecutive patients attended in the gynecologic department of the Moncorvo Filho Hospital. The 8 cases were 2 of salpingitis, 2 of endometrio-annexitis, 1 of pelviperitonitis, 1 of salpingo-oophoritis, 1 of endometritis and 1 of cervicitis. In all those cases the provisional diagnosis was made on the basis of the clinical history and the physical examination (e. g. adnexal inflammatory process, amenorrhea, precarious general condition). But the final diagnosis was always made through the microscopic examination (endometrial biopsy or pathologic examination of material removed at operation). The low age of all the patients is worthy of note: 19, 20, 20, 23, 24, 25, 26 and 35 years.

Brief Items

Dr. R. David de Sanson, professor at the University of Rio de Janeiro, has been elected president of the National Academy of Medicine.

The fourth Brazilian Congress of Cardiology will be held in September at Salvador, state of Bahia.

Correspondence

CHOLESTEROL IN THE DIET AND CORONARY DISEASE

To the Editor:—In The Journal August 2, page 1197, Dr. William Dock commented on my recommendation in The Journal of June 7 for a soft diet, including eggs, during the immediate recovery period from myocardial infarction. My recommendation is designed for the immediate recovery period and not as a long range program of management. During that limited period it appears inconceivable that a blood cholesterol level could be altered by the strict limitation of ingested cholesterol.

In the dietary program for myocardial infarction used in my hospital service for the last three years there is a paragraph which reads "after two or three days of this soft diet the indications are to limit the amount of fat, not only because it increases gastric emptying time, but also because there is often a disturbance in cholesterol metabolism associated with coronary disease." It is my established policy to keep people with chronic coronary disease on a low fat intake and to limit their cholesterol intake by advising but one egg a day.

I discussed this problem in a paper entitled "Thoughts on the Prevention of Coronary Disease" (*J. Missouri M. A.* **39**:162 [June] 1942). I have noted the tendency to high cholesterol blood levels in the average middle aged coronary subject and therefore advise these patients to partake not only of a low caloric diet but one particularly low in fats and cholesterol rich substances, such as egg yolks. There is a difference between a dietary program suitable for a short period of convalescence from an acute myocardial infarction and a long-term plan of dietary control designed to defer the further development of atherosclerotic changes.

O. P. J. Falk, M.D., St. Louis.

STREPTOMYCIN TOXICITY

To the Editor:—In the article on Streptomycin Toxicity by my associates and myself in The Journal, June 21, a statement was made that the highly purified streptomycin used in the study was first crystallized in the form of the calcium chloride double salt and "then converted by mild treatment to the sulfate to ensure stability."

It has been brought to my attention that it might be inferred from this statement that the calcium chloride double salt of streptomycin is less stable than the highly purified sulfate. It was not intended to convey any such impression; I am reliably informed that no significant difference exists in the stabilities of these two salts of streptomycin.

Walsh McDermott, M.D., New York.

MONGOLISM

To the Editor:—In an editorial in The Journal, July 26, the statement is made that mongolism is congenital but not hereditary. You urge that physicians be on the watch for a history of infections in the mother. Frequently a mother gives birth to twins with but 1 of them affected. One must conclude that infection was not the cause, since it would have affected both twins, or that the twins responded differently to a common stimulus. In that even the differential response is traced back almost inevitably to genetic factors.

Although direct hereditary descent from parent to child is not known in mongolism, the evidence derived from a study of twins is strongly in favor of there being a genetic factor for mongolism. In all instances in which twins have exhibited mongolism in one or both of the members of the pair, monozygous twins always show both affected, and dizygous twins almost always show but 1 affected. There are 4 instances of dizygous twins reported with both affected. This is not to be wondered at, as there are a number of families on record in which several sibs have mongolism, two families at least with 3 mongoloid children each. The sharp separation of monozygous twins from dizygous twins with the monozygous falling into the group of both affected, and dizygous for the most part into the group with but 1 affected, speaks strongly for a genetic basis for the condition. This is exactly what would be expected if mongolism, which so seldom shows familial distribution, were based on genetic factors. This does not preclude extrinsic factors from playing a role also.

Madge T. Macklin, M.D., Columbus, Ohio.
Research Associate, Ohio State University.

TOXIC ACTION OF EMETINE HYDROCHLORIDE

To the Editor:—With regard to the editorial comment "Toxic Action of Emetine Hydrochloride on the Heart" in The Journal July 19, it may be pertinent to recall my article in the *Journal of Chemotherapy* in January 1929 entitled "Treatment of Chronic Human Amebiasis," in which I wrote "We have come to feel that the best criterion for the limit of tolerance in giving ipecac, and more particularly emetine hydrochloride, is pulse rate, and that administration of the drug must cease entirely if the pulse reaches a rate of 100 to 110 per minute while the patient is ambulatory."

For some years I have tried to keep the pulse rate under 90 per minute each day and the period of daily dosing within two weeks. If the patient tends to be "intolerant" of emetine hydrochloride according to such controls, I stop it entirely. Then no new attempt is made to use this drug for an interval of three to four months.

In my opinion pulse rate is a valuable guide in the administration of emetine hydrochloride.

Luther M. Boyers, M.D., Berkeley, Calif.

DESTRUCTIVE CHANGES PRODUCED BY RADIUM AND ATOMIC ENERGY

To the Editor:—I note that a medical board has been appointed to give medical guidance to the various developments in the field of atomic energy. I should like to bring to your attention that in 1936 the American Medical Association Committee on Therapeutic Research, Council on Pharmacy and Chemistry, gave a grant to the Long Island College of Medicine so that I could produce in animals the destructive changes to the tissues that result from the ingestion of radioactive substances (radium poisoning). Although treatment to reverse this deadly process was our primary problem, all our animals died before the therapeutic plan could be instituted. Recently reviewing our original report published in the *American Journal of the Medical Sciences* in May 1936, and comparing it with the animals exposed to the destructive effects of atomic energy at Bikini Atoll, at present under study by the United States Navy Medical Corps and reviewed at the Centennial meeting of the American Medical Association at Atlantic City, I was greatly impressed with the obvious similarity of the destructive processes.

Edwin J. Grace, M.D., Brooklyn.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and the Examining Boards in Specialties were published in THE JOURNAL, Aug. 30, page 1565.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: *Examination.* Montgomery, June 22-24, 1948. Sec., Dr. D. G. Gill, 519 Dexter Ave., Montgomery 4.

ARIZONA: * *Examination.* Phoenix, Oct. 7-8. Sec., Dr. J. H. Patterson, 826 Security Building, Phoenix.

ARKANSAS: * *Examination.* Texarkana, Nov. 6-7, 1947. Sec., L. J. Kosminsky, Texarkana. *Eclectic.* Little Rock, Nov. 6. Sec., Dr. Clarence H. Young, 1415 Main St., Little Rock.

CALIFORNIA: *Written.* Los Angeles, Aug. 25-28. *Oral:* Los Angeles, Nov. 8-9. Sec., Dr. Frederick N. Scatena, 1020 N. St., Sacramento 14.

COLORADO: * Denver, Oct. 8-11. Final date for filing application is Sept. 20. Sec., Dr. J. B. Davis, 831 Republic Bldg., Denver 2.

CONNECTICUT: *Examination.* Hartford, Nov. 11-12. Sec., Dr. Creighton Barker, 258 Church St., New Haven.

DELAWARE: *Examination.* Dover, Jan. 13-15. *Endorsement.* Dover, Jan. 20. Sec., Dr. J. S. McDaniel, 229 S. State St., Dover.

DISTRICT OF COLUMBIA: * *Endorsement.* Washington, Sept. 8. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6012 Municipal Bldg., Washington.

FLORIDA: * *Examination.* Jacksonville, Nov. 25-26. Sec., Dr. Harold D. Van Schaick, 6675 Windsor Lane, La Gorce Island, Miami.

GEORGIA: Atlanta, Oct. 14-16. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta 3.

IDAHO: Boise, Jan. 13-15. Sec., Miss Estella S. Mulliner, 355 State Capitol Bldg., Boise.

ILLINOIS: Chicago, Oct. 14-16. Supt. of Registration, Dept. of Registration and Education, Mr. Philip M. Harman, Springfield.

INDIANA: *Examination.* Indianapolis, June 1948. Sec., Board of Medical Registration and Examination, Dr. Paul R. Tindall, K of P Bldg., Indianapolis.

KANSAS: Topeka, Dec. 3-4. Sec., Board of Medical Registration and Examination, Dr. J. F. Hassig, 905 N. 7th St., Kansas City.

KENTUCKY: *Examination.* Louisville, Sept. 22-24. Sec., State Board of Health, Dr. P. E. Blackerby, 620 S. Third St., Louisville 2.

MAINE: Portland, Nov. 12-13. Sec., Dr. A. P. Leighton, 192 State Street, Portland.

MARYLAND: *Medical Examination.* Baltimore, Dec. 9-12. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore. *Homeopathic Examination.* Baltimore, Dec. 9-10. Sec., Dr. J. A. Evans, 612 W. 40th St., Baltimore.

MASSACHUSETTS: *Examination.* Boston, Nov. 18-21. Sec., Dr. H. Q. Gallupe, 413-E State House, Boston.

MINNESOTA: * St. Paul, Sept. 3-5. Sec., Dr. J. F. DuBois, 230 Lowry Medical Arts Bldg., St. Paul.

MISSISSIPPI: *Endorsement.* Jackson, Dec. 1947. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.

MONTANA: Helena, Oct. 6-8. Sec., Dr. O. G. Klein, First National Bank Bldg., Helena.

NEVADA: Carson City, Nov. 3. Sec., Dr. G. H. Ross, 215 N. Carson St., Carson City.

NEW HAMPSHIRE: Concord, Sept. 11-12. Sec., Board of Registration in Medicine, Dr. John S. Wheeler, 107 State House, Concord.

NEW JERSEY: *Examination.* Trenton, Oct. 21-22. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO: * Santa Fe, Oct. 13-14. Sec., Dr. LeGrand Ward, 141 E. Palace Ave., Santa Fe.

NEW YORK: *Examination.* Albany, Buffalo, New York and Syracuse, Oct. 6-9, 1947. Sec., Dr. Jacob L. Lochner, Jr., Education Bldg., Albany.

NORTH DAKOTA: Grand Forks, Jan. 6-9. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

OKLAHOMA: *Endorsement.* Oklahoma City, Oct. 28-29. Sec., Dr. F. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

OREGON: * *Endorsement.* Portland, Oct. 17-18. Exec. Sec., Miss L. M. Conlee, 608 Failing Bldg., Portland.

PENNSYLVANIA: *Examination.* Harrisburg, Jan. 1948. Acting Sec., Board of Medical Education and Licensure, Mrs. M. G. Steiner, 351 Education Bldg., Harrisburg.

RHODE ISLAND: * *Examination.* Providence, Oct. 2-3. Chief, Division of Professional Regulation, 366 State Office Bldg., Providence.

SOUTH CAROLINA: Columbia, Nov. 10-12. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

SOUTH DAKOTA: * Pierre, Jan. 20. Sec., State Board of Health, Dr. Gilbert Cottam, Capitol Bldg., Pierre.

TEXAS: San Antonio, Nov. 12-14, 1947. Sec., Dr. T. J. Crowe, 918-20 Texas Bank Bldg., Dallas 2.

UTAH: *Reciprocity.* Oct. 8. *Examination.* Salt Lake Ctiy, June, 1948. Asst. Dir., Department of Registration, Miss Rena B. Loomis, 324 State Capitol Bldg., Salt Lake City.

WEST VIRGINIA: *Examination.* Charleston, Oct. 2-4. Commissioner, Public Health Council, Dr. N. H. Dyer, State Capitol, Charleston.

WYOMING: *Examination.* Cheyenne, Oct. 6. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

---

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

ARIZONA: Sept. 16. Sec., Mr. Francis A. Roy, Science Hall, University of Arizona, Tucson.

ARKANSAS: *Examination.* Little Rock, Oct. 7. Sec., Mr. L. E. Gebauer, 701 Main St., Little Rock.

COLORADO: *Examination.* Denver, Sept. 17-18. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver.

DISTRICT OF COLUMBIA: *Examination.* Washington, Oct. 20-21. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6012 E. Municipal Bldg., Washington.

FLORIDA: *Examination.* Gainesville, Nov. 1. Final date for filing application is Oct. 16. Sec., Dr. W. M. Emmell, University of Florida, Gainesville.

IOWA: Des Moines, Jan. 13, April 13, July 13, Oct. 12. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

MICHIGAN: *Examination.* Ann Arbor and Detroit, Oct. 10-11. Sec., Miss Eloise LeBeau, 101 N. Walnut St., Lansing.

MINNESOTA: *Examination.* Minneapolis, Oct. 7-8. Sec., Dr. Raymond N. Bieter, 105 M. Hall, University of Minnesota, Minneapolis.

NEBRASKA: *Examination.* Omaha, Oct. 7-8. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, State Department of Health, Room 1009, State Capitol Bldg., Lincoln 9.

OKLAHOMA: Spring 1948. Sec., Dr. Frank Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

TENNESSEE: *Examination.* Memphis, Sept. 18-19. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis.

WISCONSIN: *Examination.* Madison, Sept. 27. Final date for filing application is Sept. 20. Sec., Mr. William H. Barber, Watson and Scott Sts., Ripon.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Food and Drug Acts: Application of Federal Act to Intrastate Sales.—The defendant, doing business as Sullivan's Pharmacy, was convicted of violating the Federal Food, Drug and Cosmetic Act and he appealed to the Circuit Court of Appeals, Fifth Circuit.

Between November 1943 and March 1944 Abbott Laboratories, doing business in North Chicago, Ill., shipped in interstate commerce to Abbott Laboratories, at Atlanta, Ga., a number of boxes containing bottles of drugs, one of them being a bottle of 1,000 tablets of sulfathiazole, which was duly labeled with a caution that they were to be used only by or on the prescription of a physician and with the name and Chicago address of Abbott Laboratories. This bottle was in September 1944, sold to Sullivan and by him transferred, in intrastate commerce, to his pharmacy in Columbus and placed on his shelves for retail sales to customers. In December two lots of twelve tablets each were taken from the bottle, placed in pasteboard pill boxes with only the word sulfathiazole (slightly misspelled) on them and sold to federal inspectors. The label on the bottle was not defaced or changed and the bottle was seen and afterward taken in charge by the inspectors.

The defendant contends that the Federal Food, Drug and Cosmetic Act was not intended to operate on retail sales over the counter after interstate commerce has ended, by one who was not the importer; that the language is not clear enough to make criminals of such sellers; and that if construed to apply to them the act is, to that extent, beyond the power of Congress.

The only interstate commerce here involved, said the court, is the transportation of bottles of drugs in boxes from Chicago to Atlanta at least nine months before the sales to the government inspectors. The boxes came to rest in Atlanta, were opened by the importer, Abbott Laboratories, and the bottles were put in their stock of drugs in Atlanta for sale. Over six months later Sullivan bought one bottle, which is conceded to have been duly labeled, and put it into his stock of drugs at Columbus for retail sales, where the bottle stayed for another three months before being broken open. If the criminal provisions relied on apply here, they apply to all intrastate sales of imported drugs after any number of intermediate sales within the state and after any lapse of time as well as to similar retail sales of foods, devices and cosmetics, for all these are equally covered by these provisions of the act. We are not able to conclude, said the court, that the act is to be so construed as to bring within these penal provisions most of the sales in all drugstores, beauty parlors, barber shops and retail grocery stores in the United States.

The general purpose of the act is declared in its simple title: "An Act to prohibit the movement in interstate commerce of adulterated and misbranded food, drugs, devices, cosmetics and for other purposes." Sullivan clearly did not receive in interstate commerce any misbranded drug, said the court, nor did he proffer delivery of any in interstate commerce. A moderately strict construction of this penal provision would confine it to shippers and importers in interstate commerce. Sullivan was a party to intrastate sales only. Section 301 (K), however, prohibits "the alteration, mutilation, destruction, obliteration or removal of the whole or any part of the labeling of, or the doing of any other act with respect to, a food, drug, device or cosmetic, if such act is done while such article is held for sale after shipment in interstate commerce and results in such article being misbranded." The labeling here was not removed or mutilated, but an act was done with respect to the drug, to wit, the removal of some of it from the labeled bottle and the placing of it in a box not sufficiently labeled under the act, after shipment in interstate commerce and while the drug was held for sale, so that this portion of the drug became misbranded. Therefore in their broadest possible sense these words may include what happened. But we are of opinion, concluded the court, that they ought not to be taken so broadly, but applied only to the holding for the first sale by the importer after interstate shipment. Since importation by merchants of all merchandise is for the very purpose of sale, the importation, as has always been held, remains incomplete till its purpose is thus realized. The words of subsection (k) "held for sale after shipment in interstate commerce" naturally refer to this first sale by the merchant importer. The attempt here made by the prosecution is to extend subsection (k) so as to make criminal all retail sales from the interstate package, though made clearly in intrastate commerce, unless the label on the interstate package which has been broken be reproduced on the retail package. We believe no grocer or druggist thus breaking an interstate package for a retail sale has understood this was necessary, and it is said this case is the first effort to apply the federal act in this way. If the "holding for sale" is held to refer to all would-be sellers, no matter where or when or in what quantities, of all foods and drugs and cosmetics which at some time had moved in interstate commerce, the field of enforcement of the act will be multiplied many times. The reason urged for so expanding it, the protection of ultimate consumers, only makes another difficulty; for while Congress may regulate interstate commerce to any extent and almost for any purpose it thinks proper, this extended application would be really a direct regulation for police purposes of what is plainly intrastate commerce, the peculiar province of the state.

Nor did the state of Georgia neglect her duty. Under the provisions of the dangerous drug act derivatives and compounds of sulfanilamide are regulated and it appears that Sullivan violated such act. It would seem that the federal inspectors should have reported such violations to the Georgia inspectors. It is probable that other states have similar laws, reducing the need for Congress to interfere thus in intrastate commerce, if it has the power.

In passing this act, Congress indicated that its main and direct concern was with "the movement in interstate commerce." Until that movement is complete and the importer has sold his original packages the state cannot interfere. Congress regulated what the Constitution directly authorizes. That is no indication of any intention to regulate intrastate commerce because of any burdensome effect on interstate commerce. It is a general rule of statutory construction that as between two possible interpretations of a statute, by one of which it would be unconstitutional and by the other valid, our plain duty is to adopt that which will save the act. Applying this doctrine, the Court of Appeals, instead of holding the pertinent provision of the act unconstitutional as being an invasion of state rights, held that the proper construction was to limit the application of section 301 (k) to the first sale by the importer after interstate commerce. Accordingly the judgment of conviction was reversed.—*Sullivan v. United States, 161 F. (2d) 629 (1947).*

Medical Motion Pictures

FILM REVIEWS

No Help Wanted. Produced in 1946 for the American Legion by the National Association of Mutual Casualty Companies. 16 mm., black and white sound, 750 feet (one reel). Showing time eighteen minutes. Procurable on loan from American Mutual Alliance, 919 North Michigan Avenue, Chicago 11.

This film tells the story of the problems faced by the disabled veteran of World War II in his effort to make a place for himself in American business and industry. It is intended to appeal to (1) employers, (2) the veterans themselves and (3) community conscious organizations. The picture is dedicated to the proposition that disabled veterans and others with physical handicaps are employable and that their employment is consistent with sound insurance principles.

As the picture opens, one senses a feeling of our tremendous postwar industrial economy. Men at work in radio shops, at the draftsman table and in the machine shop and laboratory views lead one to realize that we live in epochal times. Basket weaving days are over.

As the picture progresses "separation day" arrives, the "Purple Heart veteran" returns home and is introduced to a civilian job. Job analysis, plus proper placement, is the answer. Matching the man to the job is in keeping with the highest traditions of our great American industries. Industrial America, in peace as in war, continues to lead the world. The ever increasing tempo of American living is in the film. By the time the film ends, one is convinced that again Medicine has changed the outlook on life.

No Help Wanted is definitely geared for a wide and enthusiastic response.

The Advent of Anesthesia. 16 mm., black and white, sound, 325 feet (one reel). Showing time nine minutes. Photographed in 1933 in the "Ether Dome" of the Massachusetts General Hospital; reedited in 1946. Produced and Procurable from Mallinckrodt Chemical Works, St. Louis 7.

This interesting documentary film depicts in a dignified manner the first public demonstration of ether anesthesia on Oct. 16, 1846 by Dr. William T. G. Morton while Dr. John Collins Warren removed a tumor of the neck from Gilbert Abbot. The narrator gives due credit to the previous work of Dr. Crawford Long. The use of the original operating chair, a replica of the original ether inhaler, authentic costumes and accurate portrayal of the surgical technics of that period makes this a realistic film. The photography is excellent.

This film should be of value in the teaching of the history of medicine to undergraduate students. It would also be of interest to any group of physicians when brief historical films are desired. When a film is desired for presentation of medical subjects to lay groups, this production would have real value.

Craniotomy. Prepared in 1944 by Harold C. Voris, M.D., Loyola University Medical School. 16 mm., color, silent, 1,600 feet (four reels). Showing time sixty-five minutes. Procurable from Photographic Department, Loyola University Medical School, 706 South Wolcott Street, Chicago 12.

This film is entirely a technical film concerned with craniotomy by various technics. The first part deals with a routine exploration in a case of jacksonian epilepsy which unfortunately was negative. The two other sections of the film show the technic of what has been described as the Naffziger type bone flap, in which the scalp is first reflected and a bone and muscle flap are turned together. The exploration in this case was for an adamantinoma.

A third section of the film deals with a frontal exploration for removal of the roof of the orbit presumably for persistent exophthalmos. The technic would be of interest to medical students and perhaps to practitioners. It would not be of particular interest to neurologic surgeons. The photography is good.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Water Supply: Report of the Committee on Water Supply. C. R. Cox. —p. 555.
Epidemic of an Acute Meningoencephalitis in Giles County, Tennessee: Unusual Disease. W. C. Humbert, C. B. Tucker, K. T. Mosley and L. K. Bishop.—p. 564.

Effect of Ultraviolet Irradiation of Classrooms on Spread of Measles.—Perkins and his co-workers say that studies made in the past nine years in Philadelphia and its suburbs on the effect of ultraviolet irradiation of classrooms on the spread of measles, chickenpox and mumps in school children suggested that such irradiation has reduced the spread of these diseases, particularly measles, in the classrooms studied. Similar experiments have been undertaken in three rural centralized schools in upstate New York. Observations in these experiments did not begin until January 1945. An extensive measles epidemic in the winter of 1945-1946 makes this report possible. There were indications that ultraviolet lights in the classrooms modified the spread of measles in the classrooms. Further experimental investigation is needed.

Treatment and Prophylaxis of Diphtheria.—Top thinks that a progressive decline in diphtheria over the past two decades has had a lulling effect on some communities, with a resultant lukewarmness in diphtheria prevention. At present there is a reawakened interest in diphtheria, stimulated by a slight rise in case incidence. Antitoxin is the agent of choice in the treatment of diphtheria. Prognosis is directly proportional to the day of the disease on which antitoxin is first given, regardless of the type of organism encountered, though the gravis type of infection may be more refractory to treatment. Penicillin is not a substitute for antitoxin but under certain circumstances is an adjunct. Among antigens available for protection against diphtheria, A. P. T. is the agent of choice, given in two doses at intervals of one month to six weeks. In the presence of a declining case and carrier incidence, booster doses of antigen are necessary. Booster doses of A. P. T. are suggested at 2 years of age and again before entering school for the first time. Thereafter an unusual incidence of the disease in the community warrants one in adopting further antigenic stimulation, proceeding with caution and using plain toxoid after the age of 10 to 12 years.

Acute Syphilitic Bilateral Total Ophthalmoplegia. A. C. Esposito.—p. 686.

Absence of Valves in Veins as Cause of Varicosities.—Observations of a youth aged 20 with swelling and ulcers of the right leg are illustrative of a congenital absence of valves in the veins of a large section of the venous bed surgically removed from the right inguinal region. The superficial epigastric and pudic branches on removal and inspection had no valves. The conus, which represents the end of the femoral vein, had no valves. The saphenous vein was double—a not uncommon finding. No valves were present in the upper part of its first section. In the upper part of the second section a small, nonfunctioning remnant was present. These congenital abnormalities of valves of the vein are probably only a part of a similar abnormality in other veins not removed. The abnormality could easily explain the presence of varicosities and ulcerations in this patient. Eger and Caser in 1943 maintained that congenital absence of valves in the external iliac and femoral veins might be an important factor in the production of varicose veins. Curtis and Helms think that too often preexisting thrombophlebitis is assumed to be the etiologic agent of varicose veins. Congenital absence of valves in the larger veins of the femoral and external iliac systems should be considered in young persons.

Archives of Internal Medicine, Chicago

79:475-588 (May) 1947

*Eruptive Fever with Involvement of Respiratory Tract, Conjunctivitis, Stomatitis and Balanitis: Acute Clinical Entity, Probably of Infectious Origin? Report of 20 Cases and Review of Literature. S. N. Soll.—p. 475.

Homologous Serum Hepatitis Following Transfusion. H. S. Ginsberg.—p. 555.
*Intratracheal Penicillin Therapy in Suppurative Bronchiectasis. L. E. Siltzbach.—p. 570.

Eruptive Fever with Involvement of Respiratory Tract, Conjunctivitis, Stomatitis and Balanitis.—This syndrome has been described under a variety of terms, such as eruptive fever with stomatitis and ophthalmia, erythema exudativum multiforme of Hebra, erythema or herpes iris conjunctivae, ectodermosis erosiva pluriorificialis and Stevens-Johnson syndrome. Soll reports observations on 20 cases which were observed in military personnel. The disease is acute, probably infectious, self limited and febrile. Prodromal symptoms in the respiratory tract are followed by lesions of the skin and mucous membrane of the mucocutaneous junctions characterized by vesicles and pseudomembranes and accompanied frequently with fever and occasionally with bronchopneumonia. As regards the pathogenesis, bacteriologic observations are of no significance. There is no evidence that ingestion of drugs is a factor. Because of the prodromes in the respiratory tract and generalized manifestations the disease is regarded as air borne, systemic and probably due to a virus. The various names proposed and used are misleading in that they direct attention almost exclusively to the skin. Erythema exudativum multiforme means little in cases in which dermatologic lesions do not occur. The term "erythema pluriorificialis exudativum" is better in that it refers also to the orifices of the body, but it is too long and has only descriptive meaning. Until the causative agent is found, appropriate naming of the disease will not be possible.

Stevens-Johnson Syndrome.—Wright and his associates point out that the syndrome described by Stevens and Johnson in 1922 was designated as a "new" eruptive fever associated with stomatitis, ophthalmia, cutaneous eruption and constitutional symptoms. The syndrome deserves emphasis because tragic complications of the eyes, consisting of corneal ulceration or panophthalmitis with partial or complete loss of vision, have been frequent. These severe complications of the eyes did not occur in 9 patients treated by the authors with sulfonamides and/or penicillin. Five patients were treated with sulfonamide drugs and 4 patients with penicillin systemically or topically or both. Complete recovery without sequelae occurred in all but 1 case, in which case a mild conjunctivitis developed with slight symblepharon but no corneal involvement. Enthusiasm for any type of therapy in this syndrome must be tempered by the fact that the severity of the clinical course varies greatly and that recovery without complications of the eyes is not uncommon. In 6 of the 9 cases at least one previous attack was experienced without permanent ocular damage.

Intratracheal Penicillin Therapy in Bronchiectasis.—According to Siltzbach the surgical removal of one or more lobes of the lungs is now the accepted treatment for chronic suppurative bronchiectasis. About half the patients with this ailment are unable to undergo operation because their lesions are too extensive or because they are poor surgical risks. In the treatment of 13 patients with chronic suppurative bronchiectasis and 1 patient with suppurative pneumonia, atelectasis and early bronchiectasis intratracheal instillations of penicillin were given. Ten of the 13 patients with chronic bronchiectasis had a drop of 50 per cent or more in the volume of sputum. Three patients had no significant reduction of sputum after the instillations. Recurrence of symptoms was experienced by 4 patients, with a favorable immediate response. Intratracheal penicillin therapy appears to be a useful adjunct in the preparation of patients for lobectomy. It reduces the volume of sputum, renders it less purulent and abolishes the odor. Some patients unsuitable for surgical intervention obtain fairly lasting ameliorative effects from the therapy. One patient with suppurative pneumonia and atelectasis of more than three months' duration experienced immediate and lasting clearing and reexpansion of two lobes after intratracheal instillation.

Effect of Training on Color Vision.—According to Gallagher and his associates, from 6 to 8 per cent of males are unable to make the proper responses to color vision tests. Efforts have been made to improve the color vision of these subjects. It was believed that many applicants failed the tests because of color ignorance, a condition which would be more amenable to treatment than one attributable to a disorder of color perception. At a boys' preparatory school 701 students were given a color vision test with ten of the American Optical Company's Pseudo-Isochromatic Plates. Deficient color vision was found in 49 (6.9 per cent). These 49 subjects were given training on the test plates. Perfect responses were made after training on the American Optical Company test plates by 45 members of this group, but only 6 made perfect responses to all the plates in the very similar Ishihara test. The scores on a color desaturation test did not improve. A retest on the American Optical Company plates several months later showed considerable diminution in ability to make correct responses. Training apparently does not result in the development of the ability to differentiate colors in all situations and under all conditions with the accuracy and speed possessed by those who have normal color vision.

Discovery and Evaluation of Otic Cripples.—According to Fowler, the deaf and hard of hearing are ignored as compared with other types of cripples. The handicap from blindness or from poliomyelitis is obvious; that from deafness is not. Failure to do tests or the use of antiquated methods has clouded the problem of deafness. The most serious obstacle to the establishment of routine audiometric methods for the screening and measurement of deafness and the establishment of proper standards of compensation has been the insistence of badly informed persons that the old fashioned voice and whisper tests are adequate. This has been the trouble not only in the army, the navy and the air force but also in most schools and in medicolegal courts. The audiometer has come to be recognized among experts as the most reliable standard for testing hearing.

Fowler evaluates the use of phonograph audiometers, the screening tests for groups, pure tone audiometry, pure tone bone conduction tests and fatigue tests. Spot surveys with the audiometer have indicated that half of the 140,000,000 people in the United States have some impairment of hearing.

Guillain-Barré Syndrome with Infectious Mononucleosis.—Infectious mononucleosis in which death was due to associated ascending paralysis, indistinguishable from that in the Guillain-Barré syndrome, was encountered by Ricker and his associates in 2 cases at the Army Institute of Pathology. Study of the data from these cases strongly suggests that infectious mononucleosis is one of the many diseases or agents which may precipitate or give rise to the Guillain-Barré syndrome.

Glycogen Content of Leukocytes in Leukemia and Polycythemia.—Wagner reported in a previous paper a procedure for determining glycogen in whole blood and isolated white cells. He applied the method to the study of the glycogen content of whole blood and white blood cells in leukemia and polycythemia. It is concluded from this study that the granulated leukocyte is the only carrier of glycogen in whole blood. The "reducing substances" in lymphocytes and blast cells are not considered to be true glycogen. The glycogen content of wet white blood cells in the rabbit amounts to about 1 per cent. In the human being a range of from 0.17 to 0.67 per cent was calculated. In disease higher percentages occur, in polycythemia up to 1.64 per cent and in glycogen storage disease up to 3.05 per cent.

*Rickettsialpox. M. Greenberg and O. Pellitteri.—p. 338.
Plato and Clementine. H. W. Smith.—p. 352.

Carcinoma of Lung.—Humphreys reports 125 cases of primary bronchogenic carcinoma in 109 men and 16 women between the ages of 34 and 79 admitted to a general hospital service over a six year period. In 83 of the patients diagnosis was made either at necropsy or so late in the course of the disease that no operation was considered justifiable. Of the 42 patients operated on, it was possible to carry out some form of resection in 29. Nine of these died in the postoperative period, a hospital mortality of 31 per cent. Only 3 of the 20 patients surviving resection remained alive without evidence of metastasis, but the lives of those who died of metastasis were prolonged and their symptoms were alleviated. Radiation therapy has not increased the life expectancy of 33 patients treated as compared to those untreated, but in many it has relieved symptoms and in some it has probably prolonged life. Three patients are living and apparently well without physical or economic disability three to four years after pneumonectomy. Early recognition aided by bronchoscopy is the key to successful surgical treatment.

Rickettsialpox.—According to Greenberg and Pellitteri, rickettsialpox is a new disease caused by a heretofore undescribed rickettsia. The clinical characteristic is the occurrence of a triad consisting of an initial lesion, a small papule somewhere on the body, usually without symptoms, followed about a week later by the acute onset of fever, headache, chills, sweats and backache, and thereafter by the occurrence of a papulovesicular rash two to three days after the onset of fever. The duration of illness from the onset of the initial lesion is about three to four weeks. During the acute illness there is a moderate leukopenia, and the sedimentation rate is either normal or slightly elevated. The serums of recovered patients give negative agglutination reactions with Bacillus proteus OX 19, OX 2 and OX K and give positive complement fixation tests for rickettsialpox, using the M. K. strain as antigen. The causative agent of the disease is Rickettsia akari and the vector is a rodent mite, Allodermanyssus sanguineus. There were no fatalities from the disease.

Nonrenal Hypertension. S. M. Friedman and Constance L. Friedman.—p. 655.

Globin Insulin.—According to Rabinowitch and his associates the action of globin insulin is slower than that of unmodified insulin but is more rapid than that of protamine zinc insulin. Acting more rapidly than protamine zinc insulin, it should more effectively control the hyperglycemic response to the ingestion of food. The use of globin insulin in the morning and protamine zinc insulin in the evening appeared to result in a better average control of diabetes than any of the other methods of treatment. The addition of globin insulin to the available insulins for the treatment of diabetes mellitus is fully justified.

Anastomosis Between Coronary Vessels and Internal Mammary Artery.—Beck in 1935 attempted to improve the circulation of the left ventricle by suturing a muscle graft to the surface of the heart. In 1937 O'Shaughnessy tried to bring arterial blood to the left ventricle by suturing the omentum to the ventricular muscle. Fauteux introduced ligation of the vena magna cordis in 1940. In 1946 Vineberg described an anastomosis between the left internal mammary artery and the left coronary circulation in a dog ninety-nine days after transplantation of the left internal mammary artery into the wall of the left ventricle. Vineberg and Jewett report observations on 10 dogs of which 2 showed a definite communication between the left internal mammary artery and the left coronary circulation. In 8 of the 10 animals the internal mammary artery became partially adherent to the chest wall in its former bed. Distal to this the artery was free for a distance before entering the heart. A constricting scar developed at the junction between the free arterial portion and that part of the artery which readhered to the chest wall. The artery was patent throughout in 5 animals and was patent to the site of the scar and beyond it in 2 animals. In 3 dogs it was patent to the site of the scar but thrombosed beyond it. Work is now in progress to attempt to diminish the frequency of this scar formation.

Cutaneous and Subcutaneous Hemorrhage Simulating Melanoma. L. Goldman.—p. 398.

Triweekly Arsenotherapy for Early Syphilis.—Weiner says that a triweekly method has been employed in the venereal disease clinic of the Cincinnati General Hospital and the Health Center Clinic of the Cincinnati Health Department during the past three years. A total of forty injections of the arsenical and ten injections of bismuth subsalicylate constituted the treatment. The arsenical drug (mostly mapharsen) was given in full dosage of 1 mg. per kilogram of body weight—usually 0.04 to 0.06 Gm.—three times a week for thirteen and one-half weeks, and bismuth subsalicylate in dosage of 1 cc. was given once a week during the first ten weeks. A total of 714 patients have been treated in this manner. Follow-up of these patients indicates that this regimen is safe and effective in primary, secondary and early latent syphilis. This treatment schedule is suggested as a practical office procedure. Penicillin in oil and beeswax alone or in combinations with arsenic and bismuth cannot as yet be recommended for routine use in the treatment of early syphilis.

Toxic Reactions of Penicillin.—Davis has observed several cases of unusually severe and prolonged urticaria occurring in patients undergoing penicillin therapy. Two case histories are presented to illustrate this allergic manifestation. Apparently certain individuals are capable of developing a sensitivity to penicillin either by previous fungous disease or by being in constant contact with the penicillium mold. Penicillin today is used intravenously, intramuscularly, topically (as a powder), locally as an ointment, orally, internally in serous cavities, as an irrigating agent, as an aerosol spray, as rectal suppositories, as an ingredient for vaginal douches and as "cough drops" or lozenges. Since reactions have been known to occur during the past four years when penicillin was in its infancy, we can logically expect more and varied reactions with its wholesale use in the future. Pharmaceutical houses are at present striving to produce penicillin in its purest form. The comparatively low number of reactions occurring during the last quarter of the year suggests that a more highly purified product is now available for use.

Future of Older Worker.—Klumpp thinks that society has been quite illogical in its attitude toward the older worker. There seems to be no objection to electing and appointing older persons to positions of the greatest responsibility, and yet as far as the rank and file of workers is concerned we have no objection to the imposition of blind and unselective retirement rules. Some persons welcome retirement, and the possibility of retirement on a pension should remain open for these. However, if the premise is that all persons over 65 or 70 are not worth their keep, then least of all should we permit persons above that age to occupy the top and critical positions. Among the principles that should guide the attitude toward the older worker the author mentions the following: Since hiring is selective and based on fitness to do a given job, retirement should likewise be selective and based on unfitness. Since physiologic age is not synonymous with chronologic age, compulsory retirement on a calender age basis should be abandoned. In accord with Carlson's idea, if wage in proportion to performance is recognized as a fundamental principle, the older worker should taper off in industry, just as the young apprentice gradually works himself up in skill and remuneration. If this becomes general practice, the aura of foolish pride which now stands in the way would soon disappear.

*Is Chemically Preserved Plasma Safe? A Warning! W. D. McNally.—p. 318.

Chemically Preserved Plasma.—McNally points out that most of the plasma in use at present is army and navy surplus plasma furnished by the American Red Cross. This blood plasma contains an antiseptic preservative, which is merphenyl-mercuric borate, N. N. R. This antiseptic contains 59.09 per cent of mercury. The proportion of this organic mercurial is 1 part to 50,000 plasma. This would correspond to 0.309 grain of merphenyl-mercuric borate in 1 unit of 500 cc., or 0.18 grain of mercury. Few physicians and surgeons know that this plasma contains mercury. When the patient is known to have nephritis, not over 2,000 cc. should be given, and in most serious cases without kidney damage 4,000 cc. should not be exceeded. In patients with jaundice or recently jaundiced or with cirrhosis of the liver, plasma should not be used in excess of 2,000 cc. McNally cites reports on the problem of mercurial poisoning. Blood plasma preserved with merphenyl-mercuric borate 1:50,000 is safe for patients without nephritis in the amount usually administered.

Atomic Bomb Surface Burns.—Beck and Meissner report observations on 9 Javanese who were among the prisoners of war rescued at Nagasaki. Rays from the activated atomic bomb had produced first, second and third degree thermal burns of the skin. The distribution of the burns was influenced by the position of the body and the wearing apparel of the victim at the time of exposure. It was near the noon hour on a summer day. The men were sweaty and wore as little clothing as possible; 6 men were shirtless; 2 had reduced their trousers to shorts. The body surfaces receiving the rays at right angles were more deeply burned than those receiving them obliquely. A man who had stood in such a position as to have received third degree burns on the summits of his shoulders would show second degree burns on the receding slopes of the chest and arms. The skin lesions had the appearance of ordinary third and second degree thermal burns. The parts of the body covered by the clothing were protected except for small flame-shaped zones of second degree burns. Various explanations have been given to account for these burns, but the most logical one is that the clothing, dampened with perspiration, stuck to the skin at these zones and they were burned because the insulating layer of air between the skin and the fabric was absent. Long thick hair protected the scalp, but the short hair did not protect the temples or less hairy portions of the face. There was no hematologic evidence of injury to the blood forming tissues in these patients.

Addison's Disease Followed for Nine Years.—Moehlig reports that a man aged 41, who had been followed for nine years and who had had symptoms of Addison's disease for ten years, had been treated with aqueous adrenal cortex extract, vitamin C, salt, implantation of 1,575 mg. of desoxycorticosterone acetate pellets and intramuscular injections of this substance as well as by sublingual administration. The last mentioned method resulted in swelling of the salivary glands and salivation. A change in pigmentation, previously unnoticed, occurred within six months after treatment with adrenal cortex extract and salt. Over a period of nine years there was considerable loss of pigment. It is not asserted that treatment was responsible for this loss of pigment. Several episodes of addisonian crisis occurred, requiring a stepping up of treatment dosage. Failure to take treatment for two weeks resulted in an addisonian crisis from which the patient did not recover. Death was preceded by delirium, fever and hypoglycemia (blood sugar 32 mg.). At necropsy no adrenal tissue was found anywhere! It was suggested that, as a maternal aunt had died of Addison's disease (verified at necropsy) and a niece was developing pigmentation, an adrenal anlage defect was postulated. The changes found at necropsy in the pituitary, thyroid and other organs are recorded.

Lung Changes Associated with Manufacture of Alumina Abrasives.—The disease described by Shaver and Riddell was first observed by Shaver in a young man who had been employed for eight years manufacturing an abrasive the main ingredient of which is bauxite. His chest roentgenogram disclosed a peculiar type of shadow together with a pneumothorax which had developed spontaneously. The x-ray appearances did not conform to the shadow patterns associated with lung fibrosis. When similar cases appeared, the process was investigated and 344 persons who had been exposed were investigated. Thirty-five of these had radiologic evidences of disease, and there were 13 others with lung changes classified as doubtful. The disease has been fatal in 7 instances. In several it has progressed rapidly and has produced serious disability. The cases reported by the authors apparently developed during the period when the process was accelerated for war production and the exposure increased. Cases observed in Germany seem to have occurred under similar circumstances of increased production. The disease is essentially an interstitial lung fibrosis, non-nodular in type. It may be rapidly progressive. Profound emphysema accompanies the invading fibrosis. Emphysematous blebs and bullae occur on the visceral pleura. These are apt to rupture spontaneously and give rise to pneumothorax. The etiology is doubtful, but it is known that the process involves exposure to high concentrations of alumina and silica, both in a very fine state of division, and to small quantities of many other substances.

Cryolite as Detoxifying Agent for Lead Arsenate on Plants and Animals.—Lead arsenate when used extensively, as in the Northwest apple belt, produces soil poisoning. As much as 180 pounds of lead arsenate per acre may be applied in a single season, or 1,800 pounds in a ten year period. In that area cryolite also is used on apples especially in the later sprays. Lead arsenate is known to accumulate in the soil sufficiently to interfere with crop growth. The addition of cryolite at the rate of 5,000 parts per million prevented the death of white rats when fed a diet in which 2,500 parts per million of lead arsenate was incorporated. When added to soil cryolite likewise warded off the injurious effects on beans of lead arsenate additions.

Cryotherapy for Dermatitis Venenata (Rhus).—Robinson employed refrigerants in the treatment of 101 persons who had dermatitis venenata caused by contact with plants of the Rhus family. One of these patients was treated with liquid air, 4 with solidified carbon dioxide and 96 by spraying with ethyl chloride. Liquid air produces faster results, but the handling of this substance is so difficult that its substitution for ethyl chloride is not warranted. Carbon dioxide was not quite as effective as liquid air, and its action was a little more difficult to control. Ethyl chloride produced good results without untoward side effects. Patients in whom the eruption was in the vesicular stage or in the early papular stage were treated. Severity of the cases varied from an isolated patch of vesicles on the arm or leg to the generalized form which is accompanied by fever. The vesicles dried up, the areas exfoliated and the skin healed in a relatively short time. In the majority the average duration of the disease was five days and the average number of treatments was three at twenty-four hour intervals. The extremely mild cases were often cured with one or two sprayings. Failure occurred in only 5 cases. It is suggested that frosting of the skin produces ischemia of the affected area and causes rupture of the vesicular wall with discharge of its contents. Results seem to indicate that this method of treatment may have a diversified use in vesicular dermatosis.

Dietary Factors in Cirrhosis of Liver.—In the last ten years 124 patients with cirrhosis of the liver have been treated at the research service of the Goldwater Memorial Hospital. They were given a highly nutritious diet supplemented with brewers' yeast and intramuscular injections of liver extract and thiamine hydrochloride. The diet consisted of meat and dairy foods, fruit and green vegetables. Meat was served twice and milk five times daily—three times with meals and twice in the form of milk nogs containing the yeast powder. The average diet contained 3,591 calories. The patients did well on this regimen. It generally required at least two months of treatment before significant changes appeared. Comparison was made with a series of 386 hospitalized patients with liver cirrhosis who entered five New York hospitals during the years 1920 to 1930. These patients received either no specific dietary care or they received the high carbohydrate, low protein diet which was standard treatment at the time. At the end of one year 40 per cent of the controls were alive, in contrast to 65 per cent of the treated series; at the end of five years 7 per cent of the controls and 30 per cent of the treated series were alive. Patek concludes that it is no longer justified to accept cirrhosis of the liver as a disease with a relentless downhill course. A significant number of patients with severe liver failure and a much larger percentage of patients with moderate liver damage can recover with dietary treatment.

Trypanosoma Cruzi in Treatment of Mouse Tumors.—Hauschka and his co-workers observed that infections with Trypanosoma cruzi (Brazil strain) significantly retarded the growth of squamous epithelial carcinoma 119 in A mice, mammary adenocarcinoma in C3H mice and sarcoma 37 in white mice of unknown genetic background. Spontaneous breast adenocarcinoma in C3H mice was lightly retarded in growth. The infection was more virulent in A than in C3H mice. The inhibitory effect appears to be nonspecific, since it was frequently accompanied with loss in body weight and parasitemia of vital organs such as heart, lungs and intestine. Cancer cells were rarely parasitized. Leishmanian and crithidial forms of T. cruzi were more abundant in the stroma and the connective tissue surrounding some tumors. Retardation in tumor development did not result in longer survival. Endotoxin prepared from heat killed cultures of T. cruzi (Brazil strain) was withou effect against carcinoma 119 or against transplantable and spontaneous mammary tumors. The authors conclude that the results they obtained are not to be considered as contradicting the results of the Russians, Roskin and Klyueva, as their strain of T. cruzi has not been available to Hauschka and his co-workers.

Cholecystectomy for Typhoid Carrier State.—A woman in her middle thirties had had typhoid a year before her hospitalization. During her typhoid she had been treated in a hospital for several weeks, but her stools continued positive. She was dismissed under surveillance of the public health authorities. The stool was positive for Eberthella typhosa on several occasions. During her stay of almost a month before surgical intervention, she was treated variously with succinylsulfathiazole, methenamine and penicillin, alone and in various combinations without effect. A cholecystectomy revealed a small, thick walled gallbladder containing a large number of small, many faceted stones. The stools remained positive for three weeks after the operation. Treatment with penicillin and sulfathiazole rendered the stools negative.

Toxoplasmosis.—Infantile toxoplasmosis is usually characterized by widespread destruction of the central nervous system. In surviving patients residuals such as hydrocephalus, convulsions, chorioretinitis and mental retardation are frequent. The symptoms of adult toxoplasmosis may be extremely variable, with a greater tendency to widespread involvement of the viscera than in infantile infections. It may occur as an acute febrile disease with extensive maculopapular rash involving nearly the entire body. A second type of adult infection appears as a chronic process and presents no signs or symptoms of the disease except for neutralizing antibodies in the blood. The Minnesota Department of Health Laboratories initiated neutralization tests for the toxoplasma organisms. The technic of the test is essentially that described by Sabin in which patients' blood serums are mixed with suspensions of the organism and inoculated into the skin of white rabbits. The blood specimens usually were collected from patients showing one or more of the following: chorioretinitis, convulsions, hydrocephalus, cerebral calcifications, mental retardation and encephalitis or from the parents and siblings of patients who had previously shown a positive neutralization for toxoplasma. The results of tests on 832 specimens from 761 persons indicate that toxoplasmic infections are probably widespread in Minnesota.

Trichinosis in Minnesota.—Nelson says that in January the possibility of an outbreak of trichinosis was brought to the attention of the Minnesota Department of Health. On investigation, a total of 37 clinical cases of trichinosis was disclosed. Thirty-three of the cases occurred in a small village whose inhabitants are predominantly of Central European stock, accustomed to eating sausage frequently and often raw. The majority of patients gave a history of having consumed raw smoked country sausage. The sausage had been prepared for public sale by a local butcher from trimmings of freshly slaughtered pork. No samples of the suspected sausage were available for laboratory examination. The author stresses that prevention of trichinosis is at present the concern of the consumer, and the only safe advice is to be sure that all pork is thoroughly cooked or adequately processed before consumption.

Oral Administration of Penicillin.—Ross and his associates administered penicillin orally in a total of 150 cases, including gonorrhea, subacute bacterial endocarditis, pneumonia, syphilis, cellulitis, impetigo and acute pharyngotonsillitis. The commercial penicillin tablets used in this study were effective in penicillin susceptible infections if given in sufficiently large doses. The fundamental principles of penicillin therapy when the oral route is employed do not differ materially from those attendant on the parenteral administration except for the greater oral dose required. In adults with gonorrhea, for instance, an arbitrary dosage schedule of 50,000 units of penicillin was administered every three hours for six doses, or a total of 300,000 units. No categorical statement is possible regarding the optimal oral dose of penicillin. The dosage varies from case to case, depending on the severity and the type of infection.

Pregnancy Following Splanchnicectomy for Hypertension.—Newell and Smithwick say that severe hypertension is considered by many an indication for therapeutic abortion. They report 14 cases of arterial hypertension, the pressures on admission prior to splanchnicectomy averaging 196 systolic and 130 diastolic. The time elapsing between the diagnosis of hypertension and the splanchnicectomy averaged seventy-five months. The time between splanchnicectomy and the pregnancy averaged thirty-one months, with the exception of a case in which splanchnicectomy was performed during the first trimester. Fourteen living infants were delivered. Three of the patients had so-called malignant hypertension prior to lumbodorsal splanchnicectomy. They responded favorably to operation and tolerated subsequent pregnancy well. The other 11 patients had severe essential hypertension with or without chronic pyelonephritis. These patients also are living and well following pregnancy. The hypertension was much improved over that prior to splanchnicectomy. The authors conclude that certain hypertensive women may be able to tolerate pregnancy following this operation, which otherwise would be impossible or extremely hazardous. This is particularly true in the younger age group with severe essential and even malignant hypertension.

Protamine Insulin in Diabetes Mellitus.—During the last five years Colwell has treated 150 persons who had diabetes mellitus of sufficient severity so that good balance with protamine insulin alone was unobtainable with mixtures of insulin and protamine zinc insulin. About half of the patients were less than 20 years of age at the onset of diabetes. Diets of moderate carbohydrate value were used, usually carbohydrate equal to fat in grams. Only 4 of the 150 with severe diabetes obtained poorer control with mixtures. One hundred and twenty-seven of the 146 using mixtures were balanced satisfactorily on a 2:1 mixture (two parts of regular or crystalline insulin with one part of protamine zinc insulin, both in the U-80 strength) practically always in a single dose daily. In 5 patients, 2⅓:1 mixtures and in 11 patients 2½:1 mixtures were more efficient. Three patients, all rapidly growing juveniles at about the age of puberty, obtained best control with 3:1 proportions. In not a single instance has it been found desirable to use less than 2:1 proportions or to exceed 3:1 ratios. The amount of insulin required for good control was about 10 per cent less, on the average, than with other insulins. Glycosuria was easier to avoid. Insulin shock was less frequent and not so violent. Unexpected irregularities of adjustment were less frequent. General health was better as a rule. These advantages were gained in spite of the fact that only one injection daily was required by nearly all patients.

Penicillin in Water-in-Oil Emulsion.—Kaufman treated 167 persons who had various acute infections, such as pneumonia, follicular streptococcic tonsillitis, pyelitis, sinusitis, acute otitis media, scarlet fever, streptococcic asthmatic bronchitis and furunculosis, with intramuscular injections of penicillin in water-in-oil emulsion. Treatment was given mainly at home or in the office. The extemporaneously prepared water-in-oil emulsions were less expensive and simpler to use than the beeswax-peanut oil mixtures of penicillin. Usually one injection of 200,000 units (3.75 cc. of emulsion) in each twenty-four hour period was given. In a few instances two injections a day were given. Clinical results were as effective as those obtained by the use of penicillin in aqueous solution injected every three or four hours.

Rocky Mountain Spotted Fever.—Evans and his co-workers report 70 cases of Rocky Mountain spotted fever which occurred in Ohio during the past decade. The most highly infected area is between Columbus and the Ohio River; it is more wooded than much of the terrain in other parts of the state and therefore supports better the necessary small animal reservoir as well as the tick population. Nineteen patients died. The removal of a blood filled tick from the body of a boy was strong evidence of the possibility of spotted fever. The continuation of fever beyond a week and a macular rash later becoming papular and before the end of the first week hemorrhagic should make the physician suspicious of spotted fever even though laboratory diagnostic aids are not available. The agglutination of the Proteus organism, particularly the X-19 strain, and the production of rickettsial lesions in the scrotum of a guinea pig following the intra-abdominal injection of the patient's blood may aid in diagnosis, although serial inoculations are required occasionally. Active treatment of the disease consists of antiserum, para-aminobenzoic acid and supportive measures with infusions of plasma and fresh whole blood. The yearly use of immunization is recommended in a dose of 2 cc. of Rocky Mountain spotted fever vaccine given twice at a five day interval. This is not thought to be valuable longer than one season.

*Sensitivity to Burnt Coal Gas. P. H. Mumford and G. Auckland. —p. 169.

Sensitivity to Burnt Coal Gas.—According to Mumford and Auckland, allergy to burnt coal gas, as contrasted with unburnt gas, does not appear to have been reported. Their patient was a woman aged 59 who reported recurrent congestion, *erythema and irritation o. the cheeks and eyelids over a period* of two years. Attacks were not severe till November 1945, when an intense inflammation of the face, eyelids and neck developed. This attack was accompanied with general malaise. Spontaneous recovery followed in five days. She attributed the attack to visits to her place of employment, where she and others often remarked on a burnt gas smell. The diagnosis of dermatitis due to contact with burnt coal gas was suggested by the history. Positive response to burnt as contrasted with unburnt gas showed sensitivity to some constituent of the former. Heat was shown to play no part (the negative response to a coal fire, and a gas fire with an efficient flue). There is some evidence that the minute traces of aldehydes produced by burnt coal gas were the responsible irritant

*Refrigeration *Anaesthesia.* E. S. R. *Hughes.—p. 761.*
Primary Malaria in London Children: Report of 2 Cases. C. B. Levick and M. E. MacGregor.—p. 764.

Penicillin in Osteomyelitis in Childhood.—The three series of cases *reviewed by Higgins* and his associates included 31 cases of acute osteomyelitis, 4 cases of acute suppurative arthritis and 5 cases of chronic osteomyelitis. Of the acute cases 50 per cent were in infants under 1 year old. Dosages of penicillin were relatively small—1,000 units per pound (454 Gm.) of body weight in twenty-four hours for three weeks. In acute osteomyelitis and arthritis surgery was confined to aspiration of pus. Immobilization was *partial and for short periods.* In suitable cases of chronic osteomyelitis excision of infected tissue and primary suture is advised. Mortality was nil. Complete restoration of function occurred in all but 1 of the acute cases. There was *apparent complete* healing in all the chronic cases.

Refrigeration Anesthesia.—Refrigeration anesthesia for limb amputations was introduced into the Royal Melbourne Hospital toward the end of 1944. Since then 25 lower limb amputations have been performed with the aid of this technic. The most simple technic was used. Bronchopneumonia was the most frequent complication. Hughes discusses recent opinions concerning the effects *of cold temperatures and the application* of tourniquets. He concludes that although refrigeration is a valuable form of anesthesia he does not think that it should be used for all cases of amputation. He admits that there are certain bad risk cases in which life can be saved by resort to this technic.

*Observations on Use of Benadryl in Duodenal Ulcer. A. W. Kay, L. D. W. Scott and W. E. Smith.—p. 145.
Some Aspects of Acute Pyelonephritis in Practice. J. W. Ferguson. —p. 149.
Thiouracil and Methylthiouracil in Treatment of Thyrotoxicosis. J. C. Eaton.—p. 155.

Benadryl in Duodenal Ulcer.—Kay and his associates used benadryl for duodenal ulcer in a small number of patients. Although the trial was *primarily* designed to assess the action of benadryl on gastric motility, the opportunity was taken to estimate its influence on gastric acidity, and a careful record was *made of any change in the clinical condition of the patient.* They were unable to show that benadryl has any influence on gastric motility even with doses sufficiently large to produce troublesome drowsiness. It has also been impossible to show any constant lowering of gastric acidity. Against these negative observations may be set the clinical findings. A short course of benadryl was followed by relief of all symptoms in 3 cases and by clinical *improvement in 2 cases,* leaving only 1 to be classified as a failure. But peptic ulceration with its characteristic remissions is peculiarly unsuited for therapeutic trials assessed on a purely clinical basis.

*Mepacrine and Falciparum Malaria. J. Reid.—p. 61.
Review of Chronic Intermittent Juvenile Jaundice. E. Meulengracht. —p. 83.

Quinacrine and Falciparum Malaria.—The experiments described by Reid were undertaken on volunteers in London to provide information on the correct use of quinacrine in the forces campaigning in highly malarial parts of the world. It was found that a sustained quinacrine blood level of at least 100 micrograms per liter of blood was required to prevent malaria. Blood quinacrine levels of less than 100 micrograms per liter in volunteers inoculated with sporozoites invariably resulted in a real attack of malaria with parasitemia or a transient fever without obvious parasitemia. The transient fever appeared to *be an early sign of an impending attack of malaria in non*-immune volunteers, because it invariably developed at the same time as malaria would have been expected and because malaria was transmitted on one occasion by injecting blood from an inoculated volunteer taken at the onset of transient fever. The incidence of transient fever in soldiers taking the routine dose of 0.1 Gm. of quinacrine daily for malaria prevention in hyperendemic areas would be expected to be high, because about one third of the blood quinacrine estimations in the volunteers taking this dosage were below the critical value of 100 micrograms per liter after the first six weeks. The rise in blood quinacrine *cured the fever. It is suggested that this rise is due to a* transference of quinacrine to the blood from the high tissue reserves as a result of the acidosis of fever. Serious toxic reactions from quinacrine are associated with a high blood level of the drug. Alimentary disturbances are probably due to the local action of quinacrine. They may be prevented if liberal quantities of fluid are taken. This is of particular importance in the treatment of malaria, as sweating causes dehydration. Degradation is the most important factor that influences the level of the drug in the blood. After the drug has been taken for about two months, about 70 per cent of each daily dose of *0.1 Gm. is degraded. Assessment of the value of quinacrine by* estimation of the blood levels proved superior to the older practice of assessment on a dosage basis.

*Treatment of Generalized Essential Rectocolic Polyposis. J. Charrier, P. Hillemand and L. Hartmann.—p. 5.

Solitary Abscess of Liver Due to Staphylococcus. L. Dejou and Chippaux.—p. 16.

*Hargreaves-Blanc's Method of Treatment of Chronic Amebiasis and of Its Relapse in Tropical Environment, Based on One Hundred Observations. F. Siguier.—p. 33.

Rectocolic Polyposis.—Charrier and his co-workers report 1 case of generalized rectocolic polyposis in a woman aged 22. Thirty to forty rectal and sigmoidal polypi were destroyed by electrocoagulation when treatment was started. This was followed by ileosigmoidostomy and one month later by colectomy. Rectal hemorrhages recurred three years later and small polypi were destroyed by repeated electrocoagulation. Rectal hemorrhages recurred again three years later resulting from new polypi which were not accessible to endoscopic control or treatment. Resection of the colon and of the rectum was done in two stages, the first abdominal, the second perineal. Anastomosis of the ileum to the anus instead of an abdominal ileostomy ensured sphincteric control. Penicillin and local sulfonamide therapy facilitated primary suture of the perineal incision. Microscopic examination of the specimen revealed malignant degeneration of two polypi, one in the sigmoid flexure and the other in the rectum. It is emphasized that intervention should not be delayed until the patient has reached the state of cachexia and confluent polyposis.

Hargreaves-Blanc Treatment of Amebiasis.—Treatment of chronic amebiasis in patients from Burma and Indo-China by simultaneous administration of penicillin, sulfonamide compounds and emetine was practiced independently by Hargreaves in England and by Blanc in France. Siguier employed this method for "thrust" treatment of 100 patients with severe chronic amebiasis. For the first seven days they were given 0.42 Gm. of emetine, 1,400,000 units of penicillin and 112 Gm. of sulfanilyl guanidine monohydrate. Penicillin and sulfaguanidine were discontinued on the eighth day, but emetine administration was continued with 0.04 Gm. daily until the patient had received as many centigrams of the drug as his body weight amounted to in kilograms. The patients were not subjected to strict rest in bed, received no other treatment and were not placed on a special diet. In a few days the number of stools was reduced considerably and there was a definite improvement in the general condition. This effect was permanent in only 50 per cent of the cases, while relapses occurred in the other 50 per cent. The relapses occurred at much longer intervals, from one to three months, as compared with those of from ten to fourteen days in patients who had received only emetine treatment. The frequent association of cumulative toxicity of emetine with the dysenteric relapse could be prevented and the amebic dysentery made amenable to treatment. Penicillin and sulfaguanidine are effective in controlling the colitis of severe chronic amebiasis.

Prophylaxis of Silicosis in Mines. J. Magnin.—p. 475.

Prevention and Treatment of Silicosis.—Policard and Hanaut's experiments on rats demonstrated that the admixture of 5 per cent metallic aluminum powder or aluminum hydroxide to quartz particles may inhibit the sclerosing effect of the latter on the liver (by the intravenous route) or on the lungs (by inhalation or by intratracheal injections). The aluminum particles were accumulated in the cells containing dust, and agglomeration of those cells was responsible for the blockage of alveoli. The cells which contained the dust did not seem to be changed but appeared immobilized by the numerous particles which they contained. These observations correspond to those of L. U. Gardner on the accumulation of particles in the elements of the reticuloendothelial system and on the resulting blockage. It is suggested that this inhibitory effect results from the formation of a protective film around the silica particles, the dissolution of which may thus be prevented. One must be cautious in applying these experimental results to man. Favorable results have so far been obtained by the application of metallic aluminum powder or of aluminum hydroxide only with regard to functional disturbances, particularly dyspnea. It is likely that these results may depend on psychologic factors, but the results nevertheless justify the continuation of methodical and impartial trials.

Inaugural Lecture on Induction into Chair for Medical Pathology. R. Moreau.—p. 965.

*Chorionepithelioma Not Preceded by Vesicular Mole. J. Ravina and B. Jamain.—p. 974.

Chorionepithelioma.—Ravina and Jamain report a case of malignant chorionepithelioma of the uterus in the absence of molar pregnancy in a woman aged 23. The patient was delivered in December 1944 at term of a normal infant. Normal menstruation occurred in February 1945. There was a period of amenorrhea between February and May 1945, followed by metrorrhagia until July 1945 and associated with loss in weight and asthenia. Metrorrhagia disappeared after six injections of progesterone. There followed a second period of amenorrhea until February 1946, when a subtotal hysterectomy was performed. Microscopic examination of the uterus revealed infiltration with Langhans and syncytial cells, i. e. an atypical form of chorionepithelioma as described by Marchand. The presence of a vascular mole which might have preceded the chorionepithelioma was not demonstrated, and this holds true whether the etiologic concept of chorionepithelioma following the pregnancy terminated in December 1944 or that of chorionepithelioma following a new pregnancy beginning in July 1945 is considered.

*Cutaneous Precordial Anesthesia in Angina Pectoris and Coronary Occlusion. I. Lindgren.—p. 207.

Isolated Diffuse Interstitial Eosinophilic Myocarditis. W. Reinhart. —p. 219.

Cutaneous Precordial Anesthesia in Angina Pectoris and Coronary Occlusion.—Lindgren induced typical attacks of angina pectoris in many patients by hypoxemia or exercise. Effect of anesthesia was studied during these attacks. The anesthesia was induced with 1 per cent procaine solution without admixture of epinephrine, 10 to 25 cc. usually being used. It was found that after induction of precordial anesthesia standardized hypoxemia and exercise tests produced less pain and less electrocardiographic changes than a corresponding test without anesthesia. This may indicate that amelioration of anginal pain is accompanied with improved coronary circulation. Patients submitted to extensive cervicothoracic sympathectomy and exposed to the same functional tests before and after operation likewise show less pain and improved electrocardiograms postoperatively. Precordial anesthesia by means of a local anesthetic of long-standing action in patients with myocardial infarction has proved a valuable therapeutic agent in relieving pain in patients in whom morphine was ineffective.

Pneumoperitoneum in Treatment of Pulmonary Tuberculosis: II. Roentgenologic Symptomatology of Pneumoperitoneum. M. Boffano.—p. 45.
*Treatment of Bronchial Asthma with Pneumoperitoneum. M. Taraglio. —p. 61.

Pneumoperitoneum for Bronchial Asthma.—Taraglio treated with pneumoperitoneum 17 patients between the ages of 25 and 58 who had bronchial asthma Four patients had essential bronchial asthma, 10 patients presented an asthmatic syndrome associated with tuberculosis and 3 patients were silicotic, with tuberculous complications and an asthmatic syndrome. In the first group the asthmatic attacks with cough and dyspnea disappeared almost completely after pneumoperitoneum was repeated two or three times. In 1 case the arterial tension was reduced from 175 to 150. In the second and third groups (13 patients) the asthmatic disturbances disappeared completely in 4 patients within the first twenty days after treatment was instituted, in 7 patients the same good result was obtained in sixty days, and 3 patients were improved considerably. There was a drop in temperature, less cough was present and appetite and gastrointestinal function were improved Patients should be hospitalized for the treatment. The mechanical action of the pneumoperitoneum has a reflex and nervous effect Particular stimuli may be associated with the thoracicoabdominal relationship and supported by the existence of a reflexogenic zone in the abdomen by which the respiratory activity may be influenced.

Pathology of Hydrosaline Exchange in Infants with Reference to 1 Case of Diabetes Insipidus. E. Schwarz-Tiene.—p. 66.
Tropical Physiopathology. L. Supino.—p. 69

Acetylcholine Treatment of Schizophrenia.—Fiamberti treated 311 schizophrenic patients with massive doses of acetylcholine by the intravenous route. One hundred daily injections of 0.50 Gm. of acetylcholine bromide in 2 cc. of distilled and sterilized water or five courses of twenty injections at intervals of one week were given. Only half the dose (0.25 Gm.) was used for the first three injections of all patients and throughout the entire treatment of patients with decisive vagotonia. Complete recovery occurred in 99 patients (47 men and 52 women), 136 patients (79 men and 57 women) were improved and 76 patients (28 men and 48 women) were failures. It is suggested that acetylcholine has a direct and specific effect on the mechanism of liberation of the mediator substance by which the disturbed interneuronic transmission of the nervous impulses with the resulting dissociation may be restored to normal.

Action of Cold on Total Organism. W. Schneider.—p. 259.
*Pathogenesis of Tuberculous Meningitis. E. Achelis.—p. 262.

Prognostic Evaluation of Epidemic Hepatitis.—According to Störmer the prognosis differs in the various forms of epidemic hepatitis. In the war epidemics the cases were usually mild and uncomplicated. The disease is apparently less harmful in adults than in children, but in young and strong adults it usually takes a milder course than in older persons with less resistance. The sooner the patient comes under treatment and the more consistently the treatment is carried out, the sooner will the symptoms subside. In all stages of the disease there exists impairment of the hepatic cells with reactions on the capillary walls and regressive processes in the epithelial apparatus which finally involve the entire liver in toxic or anoxemic process. Epidemic hepatitis may be regarded as a serious impairment of the hepatic cells. The importance of the hepatic function in the intermediate metabolism indicates that a period of rest is necessary in order to facilitate the regeneration of the damaged liver cell.

Pathogenesis of Tuberculous Meningitis.—Achelis reviews observations on 200 cases of tuberculous meningitis which came up for necropsy at the Rostock Pathologic Institute between 1935 and 1945. The number of male and female patients was nearly equal. The seasonal incidence was highest in June and lowest between October and January. The disease was most frequent in children under 2 years of age. Fifteen per cent of the patients had solitary tubercles in the brain. Tuberculous processes in the vertebrae were the point of origin from which the tuberculous meningitis spread by continuation in 4 per cent of the cases. Hematogenic dissemination is of greatest importance. Occasionally, trauma may be the eliciting cause. As regards the mode of manifestation, the author differentiates 4 groups of cases: In the first group tuberculous meningitis concurred with the primary complex without other tuberculous processes. This form was seen chiefly in young children. In the second group tuberculous meningitis concurred with early generalization; this form likewise was most frequent in young children. The third group, in which tuberculous meningitis was associated with general miliary tuberculosis, was the largest. In the fourth group the tuberculous meningitis was associated with tuberculosis of certain organs, chiefly the lung, but in some of these there also existed a generalized miliary tuberculosis.

Experimental and Clinical Investigations of Recent Antihistamines and Their Effect on Allergic Diseases. P. H. Nexmand and O. Sylvest. —p. 231.

High Doses of Calciferol in Lupus Vulgaris.—Hohmann and Beening used Dowling's method of treatment in 87 patients with lupus vulgaris. The method consists in administering vitamin D_2 or calciferol in tablet form. The tablets used by Hohmann and Beening contain 30,000 international units of calciferol each. During the first week the patients are given one tablet three times daily, then for three months one tablet five times daily, and after that the dose is decreased to three tablets and then to one tablet a day. The majority of patients had been treated for years with local remedies either without effect or with only temporary improvement. The effects of calciferol treatment were fine without exception. This method gives rise to no complaints and is easy to employ.

Bakers' Eczema in Finland.—Kilpinen found that 8 of 653 bakers he investigated had bakers' eczema. This incidence of only slightly more than 1 per cent contrasts with the much greater frequency observed ten or twenty years ago. Furthermore, the symptoms are less severe now. The author thinks that an explanation for the rare incidence of bakers' eczema nowadays lies partly in the fact that bakeries use more machinery, which reduces handling of the dough by hand. Formerly, when the dough was kneaded by hand, the flour and dampness caused chapping of the surface of the skin. The flour proteins and flour improving substances were enabled to influence through the small openings the deeper tissues of the skin, gradually effecting the sensitization of the skin to these substances. Another noteworthy factor is the decrease in the use of the persulfates.

Book Notices

Rh: Its Relation to Congenital Hemolytic Disease & to Intragroup Transfusion Reactions. By Edith L. Potter, M.D., Ph.D., Assistant Professor of Pathology, Department of Obstetrics and Gynecology, the University of Chicago and the Chicago Lying-In Hospital, Chicago. Cloth. Price, $5.50. Pp. 344, with 65 illustrations. Year Book Publishers, Inc., 304 S. Dearborn St., Chicago 4, 1947.

Since Landsteiner and Wiener announced the discovery of the Rh factor in January 1940, papers related to the factor and to its applications have been appearing at an ever increasing rate. Seven hundred items are listed in Dr. Potter's book. Even those especially interested in the subject have difficulty keeping abreast. Dr. Potter's monograph appeared at a very opportune moment when the need for a survey became extremely acute.

The first chapter, a general survey, is a twenty page summary and seems to have been placed at the beginning as a realistic concession to those who like to start a book by reading the summary usually found at the end. The historical background is presented in the second chapter. The immunologic relations of the Rh antigens and antibodies are covered in chapter three. This phase of the Rh factor is the most difficult to present to the noninitiated, and some writers have succeeded in making it so obscure that many turn away when they hear the topic mentioned. Potter's presentation is admirable in its lucidity and logic of development. The chapter can be recommended as the best antidote to those who have become confused by other writings on immunology of the Rh factor.

The subject of chapter four is the Rh factor in transfusion reactions. Chapter five deals with hemolytic disease (fetal erythroblastosis). The author's special experience in this field is apparent in her masterful handling of the various phases: clinic, diagnosis, pathology and treatment. The technic of Rh testing is treated in the last, sixth, chapter. The sixty-five illustrations are excellent.

It is fortunate that the first monograph on the Rh factor has been done so exceedingly well. Physicians will find here a clear, critical and fascinating presentation of one of the most talked of subjects of modern medicine.

Psychological Research in the Theaters of War. Edited by William M. Lepley Associate Professor of Psychology, Pennsylvania State College, State College, Pennsylvania. Army Air Forces Aviation Psychology Program Research Reports, Report No. 17. Cloth. Price, $1. Pp. 202. Supt. of Doc., Government Printing Office, Washington 25, D. C., 1947.

Before the United States entered World War II, psychologists had begun to work out technics of selection of combat crews. Their technics tested aptitude and intelligence and were considered highly successful, although validation was never scientifically achieved. These psychologists so completely sold their services to the air forces that the utilization of psychiatrists for the study and treatment of emotional disorders was greatly neglected. The cost in man power was probably greater than that saved through psychologic selection. The present volume represents the type of psychologic research that completely excludes the dynamic emotional factors responsible for failure in combat. There are dozens of statistical tables concerned with scores, validated by the adage that this is a scientific or score keeping age, and if one doesn't keep score one never knows the score. The editor admits that the evidence presented is at once tenuous and massive and that few of the validity indexes considered by themselves are impressive. This book represents the results of a worldwide investigation at tremendous cost in money and personnel. Its results seem hardly commensurate.

Functional Cardiovascular Disease. By Meyer Friedman, M.D., Director, Harold Brunn Institute for Cardiovascular Research, Mt. Zion Hospital, San Francisco. Cloth. Price, $3. Pp. 266. Williams & Wilkins Co., Mt. Royal & Guilford Aves., Baltimore 2, 1947.

This book proposes a new name, "functional cardiovascular disease," for neurocirculatory asthenia, and a new unproved theory, "corticohypothalamic imbalance," to explain it. The disorder already has too many names and the necessity for a new name is not clear. It seems particularly unfortunate to rename a disorder with multiple manifestations for its cardiovascular symptoms alone. The theories of "corticohypothalamic imbalance" and "cortical recession" are rather vague and are offered without benefit of any neuropathologic examinations of either the cortex or the hypothalamus. Much is made of the idea that the patients have fever. This idea is against general clinical experience; it is poorly documented, using the statistical artefact of comparing the mean maximum temperature of the highest 11 of 30 patients with that of the whole group of 11 controls. At that, the slight difference in maximum temperature between patients and controls is not statistically significant, the significance ratio, which the author did not present, being 0.98, not significant. Giddiness in the disorder is explained by "cerebral anemia," but no data are presented to show that there really is "cerebral anemia." Excursions of the pulmonary artery, abnormal in size, were described in connection with giddiness; the method of making this difficult measurement and adequate control data are not presented. It should be emphasized that this type of neurologic and physiologic theorizing is no more valid than the vast amount of psychologic theorizing which abounds in this field. The presentation of tables and the use of some modern physiologic methods may present the uncritical reader with the illusion that all the assertions are scientifically proved. A method of treatment is recommended, but there are no adequate follow-up studies or control studies to tell us whether the patients are better, worse or the same after treatment. In general, this work does not have relevant conclusive evidence for the assertions made and gives evidence of being hastily prepared.

Retinal Structure and Colour Vision: A Restatement and an Hypothesis. By E. N. Willmer, Sc.D. Cloth. Price, $4.50; 21s. Pp. 231, with 78 illustrations. Macmillan Company, 60 Fifth Ave., N. Y. 11; Cambridge University Press, Bentley House, 200 Euston Rd., London, N. W. 1, 1946.

In this technical but interesting work the author reemphasizes the fact that there is no histologic explanation to satisfy the functional requirements of the trichromatic theory of color vision of Helmholtz and Young. This theory would require three retinal receptor elements, when, as a matter of demonstrable fact, there are only two such elements known, namely the rods and the cones. Willmer reviews the known facts, and then by modifying certain proved data, particularly the photoptic curves of Abney, he builds up a very interesting and plausible theory of color vision which accounts for many of the phenomena of color vision purely on the basis of the rods and cones as receptors. As the author recognizes, there are certain phenomena which cannot be accounted for on the basis of the thesis he has developed, particularly the central perception of blue light. To satisfy these phenomena Willmer postulated the existence of a type of rod occurring in the foveal area, anatomically not differing greatly from the cones found there, which he calls "day-rods" in contrast to the more typical rods occurring in the periphery. Because of the technical aspects of the subject and of the way it is developed, this book will not be of great use to clinical ophthalmologists. To any one particularly interested in color vision it will stand as a stimulating and thought provoking piece of work.

Practical Physiological Chemistry. By Philip B. Hawk, Ph.D., President, Food Research Laboratories, Inc., Long Island City, N. Y., Bernard L. Oser, Ph.D., Director, Food Research Laboratories, Inc., and William H. Summerson, Ph.D., Associate Professor of Biochemistry, Cornell University Medical College, New York City. Twelfth edition. Fabrikoid. Price, $10. Pp. 1,323, with 329 illustrations. Blakiston Co., 1012 Walnut St., Philadelphia 5, 1947.

A comparison of the preceding edition of this textbook with the present edition indicates a number of revisions and additions in keeping with the rapid recent advances in the field of biochemistry. The presentation of the material closely follows the pattern of previous editions of the book, in which the factual and theoretical considerations are presented, followed by laboratory tests and exercises. References are included at the end of each chapter. Among the new material presented are discussions on enzymes, isotopes, colorimetric analyses and electrophoresis. The description, diagrams and explanations of the use of modern laboratory equipment, such as photoelectric colorimeters and the Warburg apparatus, are valuable additions. The authors have increased the accuracy and scope of the material presented by obtaining the aid of a number of authorities in various phases of biochemistry. These contributors have in some cases supplied complete new chapters and in other instances have revised certain sections. The edition is a valuable reference book and one of the better textbooks. While the methods included in the book are satisfactory as laboratory exercises, they are in many cases not the methods of choice for investigational work. The book is presented in an understandable and logical manner, is well printed on good material, and will undoubtedly find much use, like previous editions, as a textbook and reference work for biochemistry.

Recent Trends in Alcoholism and in Alcohol Consumption. By E. M. Jellinck, Sc.D., Director, Section of Studies on Alcohol, Laboratory of Applied Physiology, Yale University, New Haven, Connecticut. [Published simultaneously in the Quarterly Journal of Studies on Alcohol, Vol. 8, No. 1, June 1947.] Paper. Price, 50 cents. Pp. 42, with 4 illustrations. Distributed by Quarterly Journal of Studies on Alcohol, Box 2162 Yale Station, New Haven, Conn., Hillhouse Press, 432 Temple St., New Haven, Conn., 1947.

This timely and competent study attempts to answer these important questions now in the public mind: What is the trend of alcohol consumption? What is the percentage of alcoholic addicts in our adult population? According to Dr. Jellinek, the consumption of alcoholic beverages in the population below 15 years of age is so negligible that for practical purposes it may be disregarded. On the basis of all the data and statistics now available, the consumption of alcohol rose steadily during World War II. The percentage increase in the number of alcoholic addicts is less in the female than in the male adult population. The rates of chronic alcoholism appear to be determined by unwritten social controls rather than by legal control factors. The trend of deaths from alcoholism is no index of inebriety. It reflects the progress of medicine in the treatment of this disease. As to states, the adult citizens of California consume more alcohol than do the adult citizens of North Carolina. But, curiously, the adult population of the District of Columbia tops even the people of California. In presenting this critical analysis of existing information of significant aspects of the medical and social aspects of the alcohol problem Dr. Jellinek has done a distinct service to society and to the medical profession.

Nurse-Patient Relationships in Psychiatry. By Helena Willis Render, R.N., Chief Nurse, Iowa State Psychopathic Hospital, Clarinda, Iowa. Cloth. Price, $3. Pp. 316, with 9 illustrations McGraw-Hill Book Co., Inc., 330 W. 42d St., New York 18, 1947.

This book represents a carefully prepared, well written manual intended to stimulate the betterment of psychiatric nursing care. Not only has the author done an excellent piece of work but the reading of her book should stimulate further study from the extended bibliography which is listed after each chapter. The book may profitably be read by all nurses as well as those engaged in psychiatric nursing for the reason that psyche and soma cannot be separated and every somatic case presents some psychologic manifestations just as many purely psychologic or emotionally disturbed patients may present problems of a somatic nature. As the author states, "Psychiatric nursing is not unique; the details are common to all good nursing. Yet when a patient in a general hospital becomes mentally ill, how many nurses realize that they can offer the patient everything that nurses in a hospital for the mentally ill can, except perhaps a window out of which he cannot escape?"

Radiology for Medical Students. By Fred Jenner Hodges, M.D., Professor and Chairman, Department of Roentgenology, University of Michigan, Ann Arbor; Isadore Lampe, M.D., Associate Professor, Department of Roentgenology, University of Michigan, and John Floyd Holt, M.D., Assistant Professor, Department of Roentgenology, University of Michigan. Cloth. Price, $6.75. Pp. 421, with 103 illustrations. Year Book Publishers, Inc., 304 S. Dearborn St., Chicago 4, 1947.

This excellent little volume by the senior members of the department of roentgenology of the University of Michigan is faithful to its title and should prove to be a popular textbook in this phase of medical education. American educators are coming to realize that radiology, like pathology, must be taught to all medical students, not merely to those intending to specialize in the field, though of course it does not follow that the time devoted to the subject, the teaching methods or the textbooks should resemble those in pathology. Daily contact with radiology in the wards, in clinics and on rounds is of fundamental importance, but there is a place also for a certain amount of classwork, and this textbook is aimed squarely at the needs of such classes.

The diagnostic portion does not pretend to be and is not, in fact, an atlas or reference work, but its 250 pages do provide all the didactic instruction in radiology that is really needed by the physician who is not specializing in this field. The material is presented logically, and skill has been applied to the deletion of nonessentials so as to keep the whole well within the scope of the medical student, busy though he may be with other important phases of the crowded medical curriculum.

The illustrations, which are such a vital part of any book on radiology, are reasonably plentiful and for the most part good, but they would be more helpful to the student if they were larger and if more of them carried legends. The authors' deliberate policy of using no legends and keeping each illustration as close as possible to the textual reference requires small illustrations and at best merely avoids repeating in the legends material already dealt with in the text. Actually, of course, repetition is a cardinal virtue in pedagogy and in addition legends would be conducive to "browsing," which is all but impossible with the present format.

The 150 pages on radiation therapy deal admirably with this phase of radiology, and the illustrations are provided with informative legends. This portion of the book probably will appeal not only to medical students but also to young physicians, including those just embarking on a career in radiology.

Uterine Contractility in Pregnancy: A Study of the Contractions of Pregnancy and Labor under Normal and Experimental Conditions. By Douglas P. Murphy, M.D., F.A.C.S., Assistant Professor of Obstetrics and Gynecology and Research Associate in the Gynecean Hospital Institute of Gynecologic Research, University of Pennsylvania, Philadelphia. Fabrikoid. Price, $5. Pp. 134, with 64 illustrations. J. B. Lippincott Co., 227 S. 6th St., Philadelphia 5, 1947.

The reading of this volume gives one the impression that many of the chapters were written entirely separately and were later compiled to form a book. The unique use of conclusion or summary at the end of each chapter is impressive. The many tables and graphs are prima facie evidence of the author's extensive investigation of uterine contractility. The book can be recommended for one who is interested in studying the frequency and types of uterine contractions, particularly those who may be interested in the muscular behavior of the human uterus in advanced pregnancy, prodromal labor and parturition. The uterine motility is only one important factor in labor. Consequently this publication is recommended only for its merit of basic study and not for routine clinical use.

Confrontations radio-anatomo-cliniques. I. Publiées sous la direction de M. Chiray, R.-A. Gutmann, et J. Sénèque. Paper. Price, 370 francs. Pp. 55, with 98 plates. G. Doin & Cie, 8 Place de l'Odéon, Paris 6^{e}; Masson & Cie, 120 Boulevard Saint-Germain, Paris 6,^{e} 1946.

This is the first of what is evidently intended to be a series of publications in which the editors plan to correlate the radiologic, anatomic and clinical contributions toward the solution of diagnostic problems. The title indicates the plan: (1) a brief history of the case; (2) reproduction of the roentgenograms on which the diagnosis has been based or which, as is perhaps more intriguing, have led to diagnostic error; (3) to add then the operative specimen and to discuss the case as far as it is useful in relation to the laboratory findings. The material is selected from the regular monthly medical clinics which are held under the common direction of the authors. The first volume includes a discussion of esophageal varices, diaphragmatic gastric hernia with volvulus, false aspect of gastric cancer due to perigastritis, chronic ulcerative gastritis, hour-glass stomach and other similar interesting gastrointestinal clinical reports. Of great interest are the case of syphilitic hour-glass stomach and a series of gallbladder and common duct studies. Altogether 30 cases are included in the fifty-four pages of text. The illustrations are numerous and beautifully reproduced on excellent paper. We shall look forward to future numbers in this series.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

BLOOD SUPPLY OF LUNGS AND SUSCEPTIBILITY TO TUBERCULOSIS

To the Editor:—*The theory that the standing or sitting position reduces blood flow in the upper parts of the lungs and so favors the growth of tubercle bacilli is understandable. Could you inform me what is the reason that the secondary tuberculous infection has a preference for the apical lung regions but that the primary tuberculous infection does not show this preference? In the case of childhood tuberculosis the reason can be the lesser height of the blood column in the chest; but why do we miss this preference also in the primary tuberculous infection in adults?* J. C. J. Burkens, M.D., Meppel, Netherlands.

ANSWER.—Facts have not been established to answer this question. The subject has been one of long and frequent discussion and numerous controversies. Many theories have been advanced, but they are still theories. That standing or sitting positions reduce blood flow in the upper parts of the lungs and so favors growth of tubercle bacilli is opposed by those who maintain that the circulation is better in the apex than in the remainder of the lungs and affords greater opportunity for the establishment of hematogenous infections. It is true that primary lesions may develop anywhere in the lungs of adults just as they do in children. However, although children rarely develop the reinfection chronic type of pulmonary tuberculosis, when it does occur there is a definite preference for the upper parts of the lungs. There is no known physiologic or anatomic difference between the lungs of children and adults that accounts for the localization of secondary lesions in these areas.

It has been strongly argued that the relative immobility of the upper parts of the lungs makes them more susceptible to reinfections with tubercle bacilli, as those which reach these areas emain there. The defensive mechanism has better opportunity operate where there is little movement, and therefore the isease becomes chronic. In any event, collapse procedures which reduce movement usually inhibit the progress of the disease. On the other hand, there are persons who maintain that the apexes have greater mobility and therefore more bacilli reach them through the air passages. When established, the tubercle bacilli receive more oxygen, so important for their proliferation.

Some workers maintain that tubercle bacilli are brought from the cervical lymph nodes and tonsils to the apex through lymphatics which drain these areas. Once stationed in the apexes they are retained because the lymph flow from these areas is poor.

The belief has been expressed that native or acquired resistance of the individual to tubercle bacilli is important; that is, the more resistance present, the greater the likelihood of localization in the apexes. Unfortunately, this, like all other considerations, is theoretical.

TREATMENT OF HEMOPHILIA

To the Editor:—*Having as a patient a child 3½ years old afflicted with hemophilia, I would appreciate knowing whether an effective treatment or one which even alleviates partially the condition has yet been found. Thanking you for any help you may be able to offer.*

Glen W. Tuttle, M.D., Belgian Congo.

ANSWER.—Antihemophilia fractions have been prepared from human blood plasma, which, when given intravenously in doses of 200 to 400 mg., lower the coagulation time for eight to twelve hours. This gives results similar to the injection of 100 to 150 cc. of fresh citrated human blood intravenously every twelve to twenty-four hours. The coagulation time has been reduced to normal limits by the oral ingestion of 5 cc. of neohemoplastin or similar preparations once or twice daily, or the parenteral route may be used. Some patients respond to sensitization with foreign proteins, with periodic local injections of the sensitizing substance in minute amounts intradermally (Mills, C. A.: *J. Lab. & Clin. Med.* **17**:932 [June] 1932). Ovarian or estrogenic substances, recommended by some, have not given good results in the experience of all investigators. Roentgen ray irradiation of the spleen has been used, but the possibility of deleterious remote results remains to be studied.

HEART BLOCK AND ADAMS-STOKES SYNDROME IN YOUNG WOMAN

To the Editor:—*A white woman aged 19 complains of occasional dizzy spells. She has a history of having complete heart block since birth. Her heart function has always been good. She has lost consciousness on three occasions. Examination revealed a pulse of 36 and a systolic blowing murmur over the pulmonic area about grade 1 or 2. The heart was not enlarged. Blood pressure is 130/60. Laboratory studies show a mild anemia. An electrocardiogram shows complete heart block, with a ventricular rate of 30 and an auricular rate of 50. Please advise as to whether or not complete heart block is a contraindication for pregnancy in a patient like this.* Harry Parks, M.D., Atlanta, Ga.

ANSWER.—Complete heart block under the age of 30 is exceedingly rare. It is to be attributed to one of four conditions: (1) congenital defect of the bundle itself, which is usually associated with a ventricular septal defect, (2) a residual of severe diphtheria even rarer than the congenital type, (2) acute rheumatic involvement and (4) some other infectious process of virus or other nature such as has been reported in mumps.

The presence of the Adams-Stokes attacks makes this case still more unusual. It may be considered almost unique. There does not seem to be any clear proof of an etiologic factor. It sounds as if it could be congenital despite the absence of evidence of ventricular septal defect or of other congenital abnormalities.

Complete heart block, in the absence of symptoms or important complications, is not a contraindication of pregnancy, but the occurrence of what seems like the Adams-Stokes syndrome raises a serious question.

It may be well to try the effect of ephedrine or paredrine or even atropine to see whether there may be a change in the degree of block or in the ventricular rate prior to final decision. In emergency, of course, epinephrine (1:1,000) 0.25 to 1 cc. subcutaneously, repeated as needed, is the therapeutic measure of choice in the presence of recurrent attacks of Adams-Stokes syndrome.

So far as can be determined there is no previous experience with a case just like this.

KNEE-CHEST POSITION—EARLY RISING IN PUERPERIUM —MALPOSITIONS OF UTERUS

To the Editor:—*Please discuss postpartum care with particular reference to the employment of the knee-chest position and the matter of getting patients out of bed and on their feet within twenty-four to seventy hours after delivery. There seems to be much difference of opinion about the importance of this practice in the prevention or production of malpositions of the uterus and other morbid pelvic conditions. Pavey has mentioned a series of patients who were out of bed and on their feet within a matter of hours after delivery, but his practice has included the routine placement of a pessary immediately after the expulsion of the placenta, and the pessary is left in place for six to eight weeks. Others, however, seem enthusiastic about getting their patients on their feet within twelve to seventy-two hours post partum without the supporting pessary. Because early rising of certain postoperative patients has proved helpful and practical, is it fair and safe to assume that the routine may be adopted to postpartum patients?* E. G. Puterbaugh, M.D., Tipp City, Ohio.

ANSWER.—This query discusses separate items that do not have as much relationship as might appear from the wording of the preamble to the question. These are the employment of the knee-chest position (and presumably other bed exercises), early rising of puerperal patients and malpositions of the uterus.

The chief medical reasons for bed exercises are to improve circulation as an aid in avoiding phlebitis and to improve the tone and condition of overstretched abdominal muscles.

Titus (Management of Obstetric Difficulties, ed. 3, St. Louis, C. V. Mosby Company, 1945) says "It has been customary to recommend that the knee-chest exercise as a preventive of uterine misplacement is to be begun on the seventh day, although according to Eichner this is not really effective until during the third and fourth weeks of the puerperium. I agree with his view of this because of the fact that the uterus impinges against the promontory of the sacrum until at least the third week and thus is prevented from assuming a position of retrodisplacement before this time. Moreover, it may have serious consequences, as Redfield and Bodine have reported instances of air embolism following this exercise in the early days of the puerperium."

Early rising from bed, followed soon by discharge from the hospital, was begun as a wartime necessity to effect a more rapid "turnover" in crowded maternity divisions of hospitals. It was justified on the grounds of the reported good results, especially in avoidance of phlebitis, obtained by surgeons with postoperative patients ordered out of bed within twenty-four to forty-eight hours after various major operations. Many hold the opinion that this course for both types of patients is an extreme swing of the pendulum that will presently adjust itself to a more conservative midpoint.

Early rising of puerperal patients has now acquired some medical virtue, because it does not seem to have had ill effects, pelvic disorders and uterine displacements did not increase noticeably, general muscle tone did seem to be restored more promptly, and perhaps the incidence of phlebitis was diminished; moreover, the obstetric divisions of hospitals are still overcrowded!

The procedure of inserting a pessary immediately after expulsion of the placenta, referred to in the query, does not appear to be good obstetric practice and could reasonably be blamed as a foreign body carrier or excitant of puerperal infection happening in any such patient. This is too much like using a crutch for fear of becoming lame.

In direct reply to the question, it is safe to assume that reasonably early rising from bed after delivery is a proper procedure for the average, normal puerperal patient.

COPPER SULFATE METHOD OF MEASURING HEMOGLOBIN

To the Editor:—Regarding the copper sulfate specific gravity method of determining the blood hemoglobin: Do any factors other than hemoglobin content influence the results to an appreciable amount? Is there any known correlation between the behavior of the drop and the blood level in grams which would enable one to obtain the equivalent in grams?

M.D., Ontario.

ANSWER.—The description of the copper sulfate method for measuring specific gravities of whole blood and plasma should be studied carefully (Philips, R. A.; VanSlyke, D. D.; Dole, V. P.; Emerson, Kendall, Jr.; Hamilton, P. P., and Archibald, R. M.: *Bull. U. S. Army Med. Dept.*, December 1943, p. 66. Simmons, J. S., and Gentzkow, C. J.: Laboratory Methods of the United States Army, ed. 5, Philadelphia, Lea & Febiger, 1944). If the solutions of copper sulfate are prepared carefully, factors other than hemoglobin content in a whole drop of blood do not appreciably influence the estimation of the amount of hemoglobin in normal blood by this method. There is a correlation between the specific gravity of the drop and the amount of hemoglobin as expressed in grams per hundred cubic centimeters. For accurate estimations the authors advised the measurement of both whole blood and plasma or serum. However, they also maintained that useful information can be obtained from the specific gravity of the whole blood alone by using the average normal figure of 1.0264 as the value for the specific gravity of the plasma. There will be considerable error at times if this procedure is followed in pathologic conditions. In fact any laboratory equipped to carry out this method probably also will have apparatus for some other accurate method for the determination of values of hemoglobin.

AURICULOVENTRICULAR BLOCK IN MIDDLE AGED WOMAN

To the Editor:—A woman aged 46 is suffering with a complete heart block. The condition began about eighteen months ago, when her pulse rate was between 50 and 60. She felt fairly well until July 1946, when she suddenly fainted. Examination revealed a pulse rate of about 42. She began suffering with syncopal attacks for a period of about six weeks. The volume of the pulse was not regular. An electrocardiogram showed a heart block. She was given ephedrine and amphetamine preparations without apparent results. Epinephrine solution seemed to improve the syncopal attacks. On one occasion, for three days about six hours a day her pulse rate was 55 at irregular times. Since then she has been up and getting around more but her pulse rate has been gradually getting less. For the past five to six weeks her liver has begun to enlarge (chronic passive congestion). She has been taking digitalis and resting more. There seems to be some slight decrease in the size of the liver, but her pulse rate is now 23 beats per minute. The tendency seems to be downward all the time. Her weight was originally around 200 pounds (91 Kg.). She now weighs 150 pounds (68 Kg.). The etiology is apparently unknown. If there is anything known with reference to a possible improvement in the condition of the heart block, please let me know.

M.D., New York.

ANSWER.—Auriculoventricular block developing in a middle aged woman is uncommon in contrast to its occurrence in the other sex. However, in either male or female the etiology is probably coronary atherosclerosis. Less likely are such possible causes as syphilis, diphtheria, rheumatic fever or infection of other and more obscure nature. Still rarer, however, are the remote possibilities of intracardiac tumors, primary or secondary, infestations of the heart as in trichiniasis, trauma, and amyloid or other unusual diseases. However, each one of these possible causes must be thought of, and in her case with the loss of weight and vagueness of other causation cancer must be considered.

Treatment of high grade auriculoventricular block with Adams-Stokes attacks is the use of epinephrine hydrochloride 1:1,000 solution 0.25 to 1 cc. subcutaneously as often as needed. Ephedrine, amphetamine, paredrine and atropine are much less likely to be of value.

EVENTRATION OF DIAPHRAGM OR HERNIATION OF STOMACH

To the Editor:—A man aged 43 weighs 175 pounds (80 Kg.) and is 5 feet 11½ inches (181 cm.) tall; he complained for several months of persistent sticking pains in the precordium. This is not related to exercise, food intake, time of day or posture. The electrocardiogram shows regular rhythm and rate. The PR interval is 0.12. Comment on the electrocardiogram is "no definite diagnostic pattern." The general physical condition is good and there is no dyspnea or edema. Blood presure is 138/80. X-ray eventration with pronounced elevation of the left diaphragmatic dome is fully three intercostal spaces above the average normal; there is moderate gaseous distention of the hollow viscera thereunder. This elevation is also responsible for a rotation and displacement of the heart toward the right, thus being responsible for disturbance in relative measurements, the deviation to the right being proportionally greater than that to the left. Otherwise gross abnormality in cardiac contour is not discernible. The conclusion is that there is pronounced eventration of the left diaphragm with the heart rotated and displaced to the right. (The heart contour is apparently normal in consideration of the displacement.) Slight root branch thickening is present; the lung fields otherwise are clear. With repair of the diaphragm, what is the prognosis for relief from cardiac symptoms, and what of mortality in operation?

M.D., New Jersey.

ANSWER.—Herniation of the stomach, with or without other abdominal organs, through the diaphragm into the chest occurs far more frequently than eventration of the diaphragm. Fluoroscopic and roentgenographic barium studies of the esophagus, stomach and, if necessary, colon should be made in various projections in order to determine whether the elevated "diaphragm" is actually the diaphragm or herniated stomach or bowel. Surgical correction of either a diaphragmatic hernia or an eventration of the diaphragm would almost certainly cause the heart to return to its normal position and should stop the precordial pain. The mortality rate for either operation should not exceed 5 per cent if it is performed expertly by a surgeon thoroughly familiar with intrathoracic surgery. The operation for diaphragmatic hernia is, however, often performed by the abdominal route.

VENTRILOQUISM

To the Editor:—What is the mechanism of phonation in ventriloquism? Is the theory that the sound is produced using the inspired air stream correct? Some professional ventriloquists feature the ability to continue their "dummy" voice even while smoking a cigaret and, more dramatically, while drinking a glass of water. By what means is this done, particularly that of speech while drinking water?

M.D., Missouri.

ANSWER.—The art of ventriloquism was known to the ancient Egyptians and Hebrews according to archeology but derives its name from the Latin (venter—the belly; loqui—to speak) on the erroneous supposition that it came from a peculiar use of the stomach during the process of inhalation. In reality, the words are formed in the normal manner but with immobility of the visible muscles concerned with speech. The breath is allowed to escape slowly and the tones are muffled by narrowing the glottis, keeping the mouth closed as much as possible with the tongue retracted, and only its tip in motion. This pressure on the vocal cords diffuses the sound and gives the illusion of distance. The use of gestures and other contrivances to divert the attention of the listener is highly important. The art is in keeping the lower jaw immobile and diverting the attention from the speaker to his dummy and other props.

HYPERVENTILATION IN NEUROCIRCULATORY ASTHENIA

To the Editor:—I have a cardiac patient whose symptoms are caused mainly by hyperventilation. Please discuss treatment. I cannot find any adequate discussion in the literature.

M.D., California.

ANSWER.—Hyperventilation is a frequent symptom of neurocirculatory asthenia, which in turn is a symptom complex sometimes called effort syndrome, the soldier's heart and anxiety neurosis. At one time it was thought that hyperventilation alone was the cause of neurocirculatory asthenia. It is certainly an aggravating factor and produces new symptoms itself, of which the chief one is faintness.

For many years it has been known that sighing respiration has been a common manifestation of neurocirculatory asthenia. Another manifestation of respiratory abnormality is hyperventilation. Hyperventilation, of course, acts primarily through the production of respiratory alkalosis with high p_H and low pCO_2. Although it may occur in other conditions, its most common spontaneous occurrence clinically is that with neurocirculatory asthenia. Prolonged periods of hyperventilation also appear frequently in women with hysteria and in patients with severe encephalitis.

Treatment of this common type of hyperventilation is largely a matter of instruction and training to avoid the procedure itself.

It is often possible to do this by adequate coaching and by pointing out to patients that some of the symptoms are merely results of breathing too fast. Simple awareness of this fact seems to cause the symptoms to lose their frightening quality. There should be treatment also of the neurocirculatory asthenia itself.

OBESITY

To the Editor:—A woman aged 30, married and with 2 children, was very thin as a child but after puberty suddenly began to gain weight rapidly, reaching a weight of 290 pounds (132 Kg.) at the age of 20 years. She has been on a diet and has taken thyroid up to 2 grains (0.12 Gm.) three times a day and amphetamine 5 mg. three times a day for some time but has not been able to lose weight. The basal metabolic rate is — 8. At a previous hospitalization she was told by an endocrinologist that she had a pituitary type of obesity. I would greatly appreciate any information you could give me concerning the treatment of this type of obesity. Abraham B. Sand, M.D., Burlington, N. J.

Answer.—There is little, if any, basis for the diagnosis of "pituitary obesity" in modern endocrinology. Such changes in weight as accompany proved lesions of the hypophysis are always in the direction of loss of weight. It is known, however, that diseases of and physical or psychic trauma to the hypothalamus may result in obesity. When it does, it follows increased appetite. Hence the treatment of this type of obesity is similar to that of any other type of obesity in which no specific glandular deficiency can be remedied by specific endocrine therapy. That is, the intake of calories in the form of food must be reduced below the calories expended as energy. Considering the thyroid medication the patient is getting and the basal metabolic rate, one may be certain that she is not adhering to whatever reduction diet she is supposed to follow.

TETANY OF THE NEWBORN

To the Editor:—Are there contraindications to the use of intravenous calcium in tetany of the newborn? If so, what are they and what is the explanation for fatalities that have been reported?

Harry W. Orris, M.D., New York.

Answer.—According to pediatric textbooks there are no contraindications to the use of intravenous calcium in tetany of the newborn. It should, however, be given only as calcium gluconate in amounts of 5 to 10 cc. and in a 10 per cent solution. But it is doubtful whether tetany of the newborn, so called, is really a disease. It is rather a symptom complex, as cures have also been reported with dihydrotachysterol. It must always be remembered that in the frog's heart calcium ions when present in quantities above normal or when in a proportional excess over sodium and potassium ions will cause a condition of tonic contraction that has been designated as calcium rigor.

REJOINING VAS DEFERENS AFTER SEVERANCE

To the Editor:—With what degree of success can the vas deferens be rejoined after operation for sterilization? Would vitallium in the form of tube or foil, with or without thromboplastin (Parke, Davis & Co.) be of aid in the technic? M.D., Iowa.

Answer.—Before an anastomosis is attempted, an ejaculated specimen should be examined for spermatozoa because spontaneous recanalization is a possibility. Success in repairing a vas deferens cannot be obtained after a properly performed operation for sterility in which a liberal section of vas is excised. An epididymovasostomy would be the operation of choice. At best, this procedure is successful in not more than 5 per cent of cases. Since the lumen of the vas measures only 0.5 mm., it does not seem possible that anything other than a fine wire could be employed in reconstructive surgery.

LONG CONTINUED ADMINISTRATION OF TESTOSTERONE PROPIONATE

To the Editor:—A man aged 53 has been receiving testosterone propionate 10 mg. twice weekly for the past six months, claiming a sense of well being. He requests continuation of this therapy. Is there any danger in the continued administration of this hormone? M.D., New York.

Answer.—There is little danger attending the continued administration of 10 mg. of testosterone propionate twice weekly. The use of larger doses according to Grollman (Essentials of Endocrinology, ed. 2, Philadelphia, J. B. Lippincott Company, 1947, p. 491) may be accompanied occasionally with distressing symptoms—dyspnea, chest pain, palpitation and edema of the lower extremities—which require the cessation of therapy.

INSOMNIA

To the Editor:—A woman aged 49 has completed her menopause and is symptom free. Since 1930, when she had a spinal fusion done, she has suffered from insomnia. Almost continuously she has taken barbiturates and for the past five years has used 3 to 4½ grains (0.2 to 0.28 Gm.) of seconal nightly. A real addiction is now present. Her home life is happy and she has no worries of any kind, except the worry of sleepless nights. She has consulted numerous medical men, and the net result in each case was more barbiturates. Physical examination is completely negative. Can you suggest a new method of approach to this problem?

Daniel B. Lynch, M.D., Albany, N. Y.

Answer.—The first thing to make clear to both the doctor and his patient is that a medicinal dose of the barbiturates taken at night to induce sleep, even to the degree of 3 or 4½ grains of seconal, will not prove harmful to her general health. It would be much better for the patient to take this medicine regularly than for her to worry each night at bedtime. Without knowing the patient, it is less easy to suggest a future line of treatment. Possibly the services of a man experienced in the technic of hypnosis would help this patient.

ENURESIS IN YOUNG WOMAN

To the Editor:—Would you please discuss the diagnosis and treatment of enuresis in a woman aged 17 years who is otherwise perfectly normal, as far as I can determine. I have heard that there is some new drug therapy for this condition but I have not been able to find it.

Clement H. Arnold, M.D., Palo Alto, Calif.

Answer.—Included in the study of enuresis there must be thorough investigation of the urinary tract, genital tract, vertebral column, neurologic system and metabolism and possibly psychologic study. Assuming that all these examinations are normal, there are a few drugs that may be used. Some rather empirical treatments can be given in addition to the drugs. The most commonly used drug is ephedrine, which, being a sympatheticotonic drug, tends to reinforce the internal sphincter. Paradoxically, atropine-like drugs are often prescribed to reduce the sensitivity of the internal sphincter. Urethral dilations and the instillation of silver nitrate solutions are adjuncts to the drug therapy.

BACILLURIA WITHOUT PYURIA

To the Editor:—I have had several cases of Escherichia coli bacilluria without pyuria. What explanation can be offered for this, assuming that the bacilluria is not a contaminant? Also what is the probable source of the infection—hematogenous or ascending?

Harry W. Orris, M.D., Bronx, N. Y.

Answer.—Escherichia coli is found not infrequently in the catheterized urine without pyuria in chronic urinary infection. In such cases the infection usually is in a dormant stage, and a state of comparative immunity may have been established. Cases of bacilluria without pyuria may be divided into three groups: those in which bacilluria is found (1) in the bladder urine only and not in the renal specimens obtained by means of ureteral catheters, (2) in one or both catheterized renal specimens only, and (3) in both the bladder and renal specimens. In the latter group the absence of pyuria would be quite rare in repeated examinations. Bacillary infection in the urine usually is of the ascending type, although in some cases it may be hematogenous.

REATTACHMENT IN IRIDODIALYSIS

To the Editor:—A soldier aged 22 sustained a shrapnel injury in 1944. He received a traumatic iridotomy or iridodialysis over a distance of about 6 mm. in the left eye. While I have never seen a reattachment of the iris base over so extensive an area, I have succeeded in reattaching it, so that the eye is now perfectly normal. Are there any cases of such reattachments on record? I. J. Cooper, M.D., New Brunswick, N. J.

Answer.—Four cases of reattachment in iridodialysis were reported by Jameson. The area of separation was 8 mm. in the first case. No mention of the extent of the lesions in cases 3 and 4 was made. Key reported 2 cases which were surgically repaired. Each involved approximately one fourth of the basal attachment of the iris. Repair of the defect by incarceration of a tiny shred of iris within a small keratome incision, without use of sutures, was advocated by Wheeler. Spaeth discusses repair employing sutures.

THE PRESTIGE OF OPHTHALMOLOGY

Chairman's Address

DERRICK VAIL, M.D
Chicago

To those who devote their professional lives to ophthalmology it is a most pleasant, exciting, interesting and absorbing field. The rewards in the happiness, gratitude and satisfaction of patients more than repay the ophthalmologists' efforts. From a humanitarian point of view it is one of the most valuable of all specialties. It is also one of the most important branches of medicine, affecting the economic welfare of the people. Those engaged in it are jealous of its prestige, but have been too busy, too self-contained, too interested in their own work and the good that they are doing to bother much about the prestige of ophthalmology. This is the correct attitude; it is only correct, however, if it is not carried too far, and it is now time to halt a bit and look around. The opportunity to present some thoughts on this subject to fellow members of the Section on this great occasion is too good to pass by.

I had the experience during the war of meeting as comrades and on common ground many experts in other fields of medicine. The experience was invaluable from many points of view, but it awakened me to the fact that ophthalmology was held in pretty low esteem by my colleagues, at least until the battle casualties began to roll in; then the ophthalmic surgeon came into his own. Those who served with various units of the Armed Forces will, I am sure, bear me out in this contention, for they must have endured, at least early in the war and perhaps all through their experiences, the feeling that ophthalmology was relegated to an extremely minor position in the overall set-up. In fact, it was not unusual for the commanding officer or the chief of surgical service to designate any unassigned officer as the eye physician or to tell the straight ear, nose and throat officer to do the eye work or, what is still worse—and it happened fortunately on but a few occasions—to turn over all the eye work to an optometrist. To be entirely fair, there were perhaps extenuating circumstances under conditions of stress to be found in the local situation in some places.

At the meeting of the British and American Army Consultants, which was held in Paris Oct. 14, 15 and 16, 1944, I was allowed but five minutes in which to present the problems of war ophthalmology and that at the very end of the meeting. I had listened for several days to a discussion of general surgical problems, many hours of which had been devoted to the relative value of the Tobruk versus the Spica splint for fractured femur. Finally, my turn came. Somewhat exasperated, I said: "Many of the hospital commanders and chiefs of surgery are not particularly interested in ophthalmology, unless they happen themselves to have an eye disease or injury, and then they want the best care possible." This statement got a laugh, but it also got the support of the distinguished guest of honor here today, Brigadier Sir Stewart Duke-Elder, then chief consultant in ophthalmology to the British Army. Sir Stewart said: "There is one point I wish to stress very emphatically. It reverts to the question of priorities again. At the beginning of the discussion today, the surgeons decided that a suitable definition for surgical priorities could be defined as 'life-and-limb-saving.' It may be argued whether it is better to die or be blinded, but I should think that there are few; myself included, who would not prefer to lose a limb then their vision. I would therefore suggest that for 'life-and-limb-saving,' then, should be substituted 'life-vision-and-limb-saving.' It should be remembered that eye casualties comprise some 4 per cent of the total casualties of war, and I think there is a tendency for the general surgeons who control the policy of surgery in the field, to forget this, or alternatively, to treat it as a side issue." That was a rather potent statement, with good results, for from then on ophthalmology was not quite the side issue that it had been.

It was not until two months before D-day that a chief consultant in ophthalmology to the surgeon general was appointed. Before that time many ophthalmic problems had been crying for solution, many costly mistakes had been made in loss of valuable time and in supplies and equipment, as well as in misplaced personnel. After that things were better, but it was almost too late. The Navy never did have a chief consultant or advisor in ophthalmology. This was because the planning policies were in the hands of the general surgeons, who had no interest or special knowledge in ophthalmology and its peculiar functions.

This feeling of my medical and surgical colleagues in the services that ophthalmology was a minor specialty, a side issue and of relatively small importance is one that is met with today in civilian life. Along with this indifference and in some cases ignorance of fellow physicians is the confusion in the public mind on what ophthalmology is and how it differs from optometry. I won't say that the prestige of this specialty is lowered particularly as a result, but at least it is actively shared

---

Read before the Section on Ophthalmology at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1947.

by a nonmedical group, with the result that all who work in this field are, in the minds of the uninformed, "eye doctors." This would be laughable if it were not so serious to the patients, in consideration of the time spent and in the quality of the differences in the training of the ophthalmologist and the optometrist. This specialty is not entirely alone in the sharing and diluting of its hard-won prestige, for in the mind of the public the psychiatrist has as his rival the pseudopsychologist or lay psychoanalyst; the orthopedic surgeon, his bone setter, osteopath or chiropractor; the physician, his naturopath and so on. This fringe, some of it lunatic, of nonmedical practitioners has always been attached to the physician's robe and has had some soiling effect on it. But what should and does concern the ophthalmologist most is the ignorance about his specialty observed in fellow physicians and the indifference they often show to his special knowledge and work. Some of the factors that I believe are responsible for this decrease in ophthalmologic influence are (1) exclusiveness and withdrawal from the general medical field; (2) exclusive and hidden work which is obscure, that is to the average general physician, and performed in special eye hospitals and pathologic laboratories; (3) the eye, ear, nose and throat specialist, who is poorly qualified in ophthalmology; (4) the optometrist; (5) rebates; (6) the gradual loss of part of the territory or field of endeavor of the ophthalmologist and of his responsibilities to the neurologist, neurosurgeon and plastic surgeon; (7) little or no representation in the controlling membership or councils of the major medical and surgical organizations (this is directly related to the first factor), and (8) spectacular publicity.

Reasons for decrease in ophthalmologic influence:

1. Exclusiveness and withdrawal from the general medical field: There is no doubt that this is true and has been evolved in direct proportion to the technical growth of the specialty. The general medical interests of the ophthalmologist have become narrower as time has gone on. Ophthalmic problems today require more skill, more diagnostic acumen, more instrumentation than ever before. If one will but compare the office practice of ophthalmology today—necessitating as it does refraction, perimetry, slit lamp biomicroscopy, tonometry, muscle studies, ophthalmoneurologic investigation, laboratory tests, ophthalmoscopy, the maintenance of careful records and so on—with the practice of a busy oculist of forty years ago, who was able to see twice the number of patients in half the time, it can readily be seen how much more complicated, and rightly so, this work is today. This sort of thing saps one's energies over a period of time, until it is no longer possible to see the forest because of the trees. Such is the demand for service from all sides, that even the new exresident soon finds himself taxed with ophthalmic work to the fullest extent of his time and ability. He thus tends to lose interest in the broader aspects of his profession as a physician and to lose touch with those colleagues, who have so much to teach that will benefit his patients, and to whom he could teach so much that would benefit theirs. The solution lies in a realization of the rut that one is in and in the devotion of more time and effort as an individual to the wide general medical interests of a true physician. The ophthalmologist must sell himself and his special skills to his general medical and surgical colleagues, not for any ulterior economic purpose but for the welfare of the medical profession as a whole.

2. Work in special eye hospitals and the laboratories of eye pathology: Special eye hospitals are not as frequently found today as they used to be. I have in mind particularly the small private eye hospitals and clinics that were relatively common in the past. The modern trend, which is wise, is to develop a satisfactory eye department in a general hospital or a special building in a center. More of this needs to be done, for the ophthalmologist must rub elbows with other physicians in his daily work and not hide his light under a bushel or fail to see theirs.

The study of ophthalmic pathology of its very nature is an ultra specialty. It requires special equipment, technics and knowledge. The average general medical pathologic laboratory is entirely unsuitable to turn out the exceedingly fine work that is needed in this specialty. Therefore the ophthalmic departments in medical schools and hospitals have been forced to develop their own laboratories. This need not be so. Ophthalmic pathologic procedures should be a part of the work of the general medical laboratory, and it is up to the ophthalmologist to educate the general pathologist to this way of thinking if he will but listen. He should, for it is to his advantage as well to have all of this work together.

3. The Eye, Ear, Nose and Throat Specialist: Eighty per cent of the members of the Academy of Ophthalmology and Otolaryngology have an eye, ear, nose and throat practice. This group, therefore, is far from being extinct. There is an obvious need for their services, especially in the smaller communities. However, it is sad to relate that many of them are better qualified by training and board examination to do ear, nose and throat work. They are satisfied for the most part with certification by the Ear, Nose and Throat Board, which gives the membership in the Academy. From then on further training in ophthalmology is casual and secondary. Few seek additional certification by the Board of Ophthalmology. These statements are supported by war experience and the records of the American Board of Ophthalmology. The solution lies i insisting that these men have a satisfactory trainin or at least opportunities for such training in the fiel of ophthalmology. There is no more certain way t lose ground with one's colleagues than through poo quality of work.

4. The optometrist: Legally entitled to practice hi technic, the optometrist is here whether one likes it o not. There is a fact that all must face: he is als protected by the legal definition of the practice o optometry in each state against the failure to recogniz a pathologic process with the eye. In spite of this lega protection of nonresponsibility he claims this power o diagnosis publicly and makes much of his competenc to recognize ocular disease. It is well known from daily experience that such competence is not the case. Many examples of this morally criminal though entirely legal lack of responsibility on the part of the optometrist can be demonstrated by every ophthalmologist. The optometrists as a whole have done everything in their

power by advertisements of the most blatant type, which assail the ear and eye night and day, to confuse and mislead the public into believing that they are eye physicians or by calling themselves eyesight specialists to claim to practice a profession having to do with all ophthalmic care. This has been going on for a long time. Therefore it is not surprising that the public should not know the difference between an ophthalmologist or an oculist, and an optometrist. What is surprising and shocking, however, is that junior and senior medical students and even physicians often do not know the difference. In fact cases are known in which a physician has referred a patient to an optometrist for an ophthalmoscopic consultation and opinion. I repeat that the ophthalmologist is at fault for the existence of such ignorance among his medical colleagues.

One must face the fact, too, that there are simply not enough ophthalmologists to go around. Eighty per cent of the persons seeking an ocular examination go to the optometrist. Of these 80 per cent it is presumed on good grounds that 30 per cent have some ocular disease. How many of these cases are missed by the optometrist it is impossible to say, although the figure must be impressive. But even if every one of these persons had sought out the ophthalmologist, the work could never have been accomplished by the small number of such specialists available. It is not a question of economic rivalry, therefore, that has led to the bitterness between the two groups, for each group has more work to do than can be done properly. Rather, it is the effort of a nonmedical group to enter into a professional field that disturbs those who are also physicians.

How then is the average person, the common man, to be protected against losing his sight as the result of nonrecognition of his ocular or general disease? I see no solution to this problem in the immediate future.

For the long run, however, I should like to consider the following suggestions: First, the ophthalmologist must take a more active part in instructing this nonmedical group in the recognition of ocular pathologic processes. This does not imply that the optometrist must be taught definite diagnosis, for I believe this to be impossible because of his lack of medical training. But I do believe that he can be taught to recognize that something is wrong and, what is more important, that he can be impressed with the moral necessity of seeing that such a patient consults an ophthalmologist, which he has been loath or reluctant to do up to the present. The teaching of the optometrist by the physician is a practice that has gone against the grain, but it is a sworn duty to protect the patient, and this responsibility must be carried out. There are some who say, "Ignore the optometrist entirely, but educate the people to seek proper eye care." This should be done too, of course, but the members of the medical profession have hitherto been reluctant to go deeply into this matter. The dear public has to have its head hammered at repeatedly in order to get any message through, no matter how right or beneficial the message may be; and the lower class of optometrists, the more numerous and noisy group, have succeeded in hammering in their message to the detriment of the people. The first thing, therefore, is to curb these unscrupulous optometric advertisers, the neon sign, jewelry store and department store artists.

This leads to the second suggestion. It is to support that small but intelligent group among the optometrists themselves, who are working and striving to elevate the ethics, standards of education and sense of duty to public welfare among their own colleagues. The blatant newspaper, radio and neon sign advertisers are repugnant to them as well as to the ophthalmologists. This group is valiant and deserves active support, for in no other way can the advertiser be driven from the field of refraction care of the public. The medical group cannot possibly accomplish this; its members have neither the time nor the legislative talents nor even the interest to attempt this by themselves. But each as an individual must seek the aid of the special ophthalmic societies and particularly the major medical societies, such as the American Medical Association, to take part in this campaign. It is a matter of expediency, for the ophthalmologist agrees with the more enlightened optometrist that the advertisers must go. Third, physicians must seek all means and measures at their command to have the title doctor reserved for doctors of medicine; the term eye doctor or eyesight specialist must be legally banned to the optometrist. This has already been done in some states. Should the optometrist succeed in the future in persuading some reputable university to put a school of optometry into its faculty and curriculum (which, incidentally, has not occurred since 1925) physicians must see to it that the degree of doctor is not granted to the graduates in optometry.

The public, too, must be educated, if at all possible, which I doubt, to know the difference between the doctor of medicine and the so-called doctor of optometry. Finally: Legislation must be sought that will hold the optometrist legally responsible for his diagnostic errors and see that he is subject to the same court of malpractice.

It has been demonstrated in the Army and Navy that optometrists and ophthalmologists can work side by side peacefully for their mutual advantage and to the advantage of the patient as well. It is therefore not inconceivable that this teamwork can be carried over into civilian life and it is to this end that all must work. For, I repeat, optometry is here and legally entitled to stay, and it is the function of medicine to absorb it, if man is to be protected and taken care of.

5. Rebates: Nothing can be said in extenuation of the widespread evil of optical rebates. It cannot be defended on ethical, moral or even economic grounds. It is a blot on ophthalmologists as professional men. They must repudiate the practice with all their strength. It is a cancer to their prestige. They have lowered themselves in the eyes of their medical brethren and in those of the persons who are aware of it. It cannot be hidden by subterfuge, and if they do try to do so, they are playing directly into the hands of the commercial firms and optometrists to the detriment of themselves and to the harm of their patients. The solution of this evil is to have none of it but to charge fees that are right and proper for the great service which is rendered, and to let the world know that rebates are not accepted.

6. The gradual loss of part of the territory or field
of endeavor of the ophthalm and o his responsi-
bilities to the neurologist surge stic
surgeon: Here again it i n fau ese

fields ophthalmologists have not made good as a group, and it must be remembered that there is no monopoly on the experienced use of the ophthalmoscope and perimeter or the neurologic examination of the eyes. The perimetric examination is slipshod and haphazard, the knowledge of neuro-ophthalmology is casual and scanty and the practice of it is worse; the ocular specialist has even failed to convince the neurosurgeon that he can excel him in ophthalmoscopic examinations.

As a group the specialist in this field has backed away from ophthalmic plastic surgery and has done little to train residents. The solution lies in more and better training in order to offer convincing proof that the ophthalmologist knows more about neuro-ophthalmology than does the neurologist and that he can do better plastic repairs of the lids and adnexa than can the plastic surgeon.

7. Little ophthalmic representation in the general medical and surgical groups: This lack of representation is a sad truth. Ophthalmology has gradually been frozen out, so that if it is considered by the councils at all, it is apt to be as an afterthought. The cause of this lies within and is connected with the aloofness of this specialty from general medicine and surgery. The cure is to take more active part in the affairs of general medical practice.

8. Spectacular publicity: Recently ophthalmology has experience a spate of spectacular and notorious publicity that in the end is harmful to its prestige. It almost seems as if there is an epidemic of publicity. Lord Horder of Great Britain, the great physician, has said, "One cannot have prestige without a certain amount of publicity, but you can have a large amount of publicity with very little prestige." It is the duty of ophthalmologists as individuals and as a group to control publicity that is spectacular and harmful, first to the patients and in the end to the physicians. The leaders in particular must be ever watchful against this pernicious seduction, for if they fall for the siren, who shall blame the younger man in whom lies all of the hope and faith and confidence for the future of ophthalmology? It takes a stern hand and even disciplinary action to stamp out. It can be controlled best only by the individual, for it is in his power to refuse press interviews that violate the confidence of the patient or to refuse medical care to the patient who does not conform to his wishes in regard to publicity or to discharge the employee who gives back-door information to the press. There can be only one guiding question asked of proposed publicity, "Is it harmful to the general good, to the individual patient or to ophthalmology?" The ophthalmologist must never permit himself to be intruded into the picture.

Recently, too, there has been medical publicity that is tinged with a political or subversive taint, the promotion of a discovery not for its merits but because of a national ideology. This is dangerous not only because the discovery may be found not to have merit and publicity may thus lead to ridicule of the responsible group or agent, but more seriously because medicine and medical discoveries must be universal and free of any tie to political propaganda. In other words, a discovery must be tested on its own merits and neither supported nor condemned because it bears an ideologic tag. One must fight against such inroads into the freedom of thought to the utmost of one's strength.

Ophthalmology deserves the love and respect of those who practice it. Devotion to this specialty is repaid magnificently and in many ways. One must be ever jealous to protect its honor, nobility of purpose and prestige.

700 North Michigan Avenue.

POLIOMYELITIS

HART E. VAN RIPER, M.D.
Medical Director, National Foundation for Infantile Paralysis
New York

Prior to 1870 poliomyelitis occurred only as a sporadic disease of the very young child. During the 1870s in Europe, the 1880s in Scandinavia, the 1890s in the northern part of the United States and the 1930s in the southern part of the United States poliomyelitis took on a new character—occurring in epidemic proportions. The reason for this transition from a sporadic to an epidemic disease is unknown, but of particular interest is the fact that with this transition there has been a gradual increase in the average age of the persons afflicted.

There is recent evidence to support this historical belief that such changes are part of the pattern of the disease. At the present time this evolution seems to be occurring in the larger metropolitan communities of Osaka and Kobe in Japan. During 1938 and 1940 these urban areas experienced for the first time severe epidemics of poliomyelitis, most of the cases appearing in the very young children.

The period of evolution from sporadic to epidemic poliomyelitis corresponds roughly with the institution of widespread measures for improved sanitation. This interesting coincidence has led to the hypothesis that the virus is more widespread in areas where the sporadic disease predominates, making possible frequent exposures of the young infant to virus during the time when he still retains a high titer of passive immunity from his mother. Exposure to the virus under these conditions would surely stimulate further resistance to poliomyelitis and only occasionally result in the production of the frank disease. This theory might explain the infrequent cases of poliomyelitis in young children as they occurred in the early history of the disease in Europe and the United States. But, in regions where epidemics predominate, people are exposed to the virus less frequently and at a later period in life, when they have lost all or most of the passive immunity acquired from the mother. Thus there results a greater chance for the development of frank disease among older age groups rather than an increased resistance.

PORTALS OF ENTRY

Knowledge as to the possible portals of entry has been acquired through the study of characteristic lesions of poliomyelitis found in ganglions of certain cranial and peripheral nerves and has been offered as suggestive evidence of the path by which the virus has invaded the brain and spinal cord. Studies on experimental animals have indicated that such lesions in the sensory ganglions may result from a centrifugal spread of the virus following inoculation of the virus directly into the brain. Even though the weight of evidence in the

---

Read in the General Scientific Meetings at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 10, 1947.

majority of cases indicates that the portal of entry is by way of the alimentary tract, it is recognized that in at least a fairly large number of cases the infection may have been via the peripheral nerves of the mouth and throat regions.

TRANSMISSION OF THE DISEASE

Many authorities believe that the greater majority of poliomyelitis infections are transmitted by intimate contact between a susceptible person and some one harboring the virus. The "some one harboring the virus" need not necessarily present clinical symptoms of the disease; indeed, there is considerable reason to believe that for every diagnosed case of the disease there may be approximately 100 symptom-free persons harboring the virus.

The fairly frequent recovery of poliomyelitis virus from feces, sewage, sewage disposal plants and flies has raised the question whether the transmission cycle may be from feces or sewage to flies, to man, with the possibility of an intermediate carrier—food. That an occasional case of the disease may be acquired by this route seems reasonable, but studies of many epidemics indicate that most cases of the disease are transmitted primarily through intimate contact.

THE RELATIONSHIP OF ANTIBODIES AND RESISTANCE TO THE DISEASE

The mechanism of immunity has perplexed investigators, because it is not unusual to find that the disease sometimes occurs in persons who have a high titer of serum antibodies; that persons recovering from a paralytic attack of the disease frequently do not show an increase in the titer of these antibodies, and, further, that monkeys recovered from a paralytic attack of the disease often show little or no serum antibody but do exhibit pronounced resistance to intracerebral injections with the same strain of virus. The general conclusion to be drawn from these apparently contradictory observations is that no relationship exists between humoral circulating antibodies and resistance to poliomyelitis.

Unfortunately most of these studies have been determined with respect to the Lansing virus, and there is no proof as yet that this virus is of great importance in the clinical disease or that the persons studied actually were infected with this strain of the virus.

Investigations designed to produce a vaccine are most intriguing and are being continued. It has been found that the monkey convalescent from a paralytic attack with the virus may exhibit little or no antibody in the circulating blood but will show high titers of antibodies in tissues of its central nervous system. Such an animal is usually resistant to further intracerebral inoculations with the same strain of virus. More recently it has been demonstrated that repeated intramuscular injections of live virus in monkeys apparently produce no clinical evidence of the disease but do result in the production of high titers of antibody in the circulating blood. When by this method there is produced an antibody titer in the circulating blood above the 1:800 level, these animals have been found to be solidly resistant to intracerebral inoculations of the virus. It would appear that, although the antibody titer in the circulating blood bears no direct relationship to resistance to the disease, there may be an antibody threshold in the blood which permits sufficient amounts to spill over into and to render resistant the tissues of the central nervous system.

THE METABOLISM OF CELLS AND RESISTANCE TO THE DISEASE

Clinicians have recognized that poliomyelitis generally is a disease of the well nourished. This observation has logically led investigators to study cell metabolism and its relation to resistance to disease. It has been found that when an anterior horn cell is regenerating a damaged axis cylinder this cell is solidly resistant to infection with the virus of poliomyelitis. Efforts are being directed toward the determination of the chemical or metabolic differences caused, on the one hand, between a regenerating cell which is resistant to the virus, and, on the other, a normal cell which is susceptible. Preliminary observations indicate that the virus of poliomyelitis may inhibit utilization of glucose by these cells. If this is true, such alteration would mean a serious loss in energy. Further studies have shown that there is a considerable derangement or disorganization of the oxygen-carrying enzymes following an infection of the nerve cells by the virus of poliomyelitis.

NEUROPHYSIOLOGIC OBSERVATIONS IN POLIOMYELITIS

Poliomyelitis was formerly believed to be flaccid paralysis due solely to destruction of anterior horn cells. Since it is now an established fact that poliomyelitis may affect most of the nerve cells in the brain and spinal cord, one would expect that the clinical signs of this disease can result from a mixture of both upper and lower motor neuron lesions.

Electromyographic studies show that the acute paralytic muscle at rest is usually electrically active as compared with the normal muscle at rest, which is usually electrically quiet. Recent reports from the Scandinavian countries differ somewhat from these conclusions in that they indicate that both the normal and the paralytic muscles at rest can be electrically inactive, although it is much more difficult and, in fact, sometimes almost impossible to put the paralytic muscle in a position in which it is electrically inactive. These observers further report that, whereas the normal muscle under voluntary contraction exhibits an arhythmic electrical discharge, the poliomyelitic muscle under voluntary contraction usually exhibits a rhythmic electrical discharge. If the latter observations are true it would indicate that the poliomyelitic patient has difficulty in performing a slow steady contraction with paretic muscle, and indeed this does seem to be the case.

NEW EXPERIMENTAL ANIMALS

The discovery some years ago that the cotton rat and the Swiss mouse could be infected with the virus of poliomyelitis raised the hopes of investigators that the availability of these animals would allow for an early solution to many of the problems of this disease. Unfortunately, it has been found that these animals are susceptible to only one strain of the virus, and that only when inoculated by the intracerebral route. These limitations have seriously hampered the studies on relation of nutrition to susceptibility and the search for chemotherapeutic agents, serums or vaccines which might offer a cure or preventive of the disease.

Recently importers have been able to bring cynomolgus monkeys from the Philippines to this country, and there is considerable hope that the susceptibility of these animals to infection by the oral route will make it possible to study with renewed effort those phases of research which have of necessity been held in abeyance.

IMPROVED LABORATORY METHODS FOR THE DETECTION OF THE VIRUS

The only available method for the detection of the virus of poliomyelitis is the inoculation into the brain of the monkey of material suspected of containing the virus. If the virus is present the animal may develop clinical and histopathologic signs of the disease. The second step is the injection of a suspension of infected nervous tissues of the first animal into a second monkey. This procedure is not only time consuming, laborious and expensive but does not always indicate the presence of minute quantities of the virus. The present procedures for concentration and partial purification of the virus are by chemical and physical means; for example, removal of fat and contaminating bacteria by ether, adsorption and precipitation of the virus by ammonium salts, and the concentration of the virus by the ultracentrifuge have vastly improved the methods for detecting minute quantities of the virus. The improvement of this test has necessitated more time consuming, expensive and complicated procedures and can be utilized only in certain special circumstances.

MAJOR PROBLEMS TO BE SOLVED

The lines of investigation that are now being pursued include the following major problems, which must be solved:

1. The development of a simple laboratory test to identify, preferably, a single virus particle.
2. Development of a simple diagnostic laboratory test to indicate whether or not infection with the virus has taken place.
3. Determination of the relative number of virus particles required to infect the human being and the laboratory animal.
4. Determination of the physical, chemical and biologic characteristics of the virus particle.
5. Determination of the number and characteristics of the different types of the virus which produce clinical disease in man.
6. Development of a full understanding of (*a*) the metabolism of the cell and of the virus, and of (*b*) how the metabolism of the virus interacts with the metabolism of the host cell to produce disease.

The solution of these problems would seem to be fundamental to the development of any particular preventive or curative measures for infantile paralysis.

TREATMENT

When there is developed a nontoxic therapeutic agent —drug, antibiotic or serum—which will be specific against all strains of the virus of poliomyelitis there may then be presented to the members of the medical profession a standardized form of treatment. Until then it must be admitted that during the acute, or communicable, period of the disease treatment is entirely symptomatic. The physician should make the patient as comfortable as possible, protect the muscles already involved by the action of the virus on the nerve cell that innervates the muscle and prevent deformity.

There are those who have attempted to establish an empirical approach to the treatment of this disease. Acute anterior poliomyelitis demands of the physician and his professional co-workers the same exercise of judgment in the administration of therapeutic measures as does any other acute infection. He must consider the patient first, the disease as secondary in importance —empiricism does not lend itself to the art or science of medicine.

RELATION OF THE PROBLEMS OF POLIOMYELITIS TO THE PROBLEMS OF DISEASE IN GENERAL

There is considerable misunderstanding with regard to the ultimate purpose behind the creation of various organizations to combat specific diseases. While it is true that such an organization is primarily concerned with the eradication of one disease, no organization could conceivably carry out its program for any length of time unless it had as its real objective the eradication of disease in general.

The function of the human body, whether in the direction of the normal or the pathologic, is guided by the metabolism of the cells which make up the organism. If the chemical processes within and between these cells go forward in continuous normal sequence in one direction, the result is normality of the person, or health. If the sequence of these chemical reactions is in any way altered, whether by nutrition, by contact with an infectious agent, by trauma or by heredity, the net result is abnormality, or disease. An intelligent approach to an understanding of disease, whether such disease is cancer or allergy, infectious or degenerative, must be based on an understanding of the complicated metabolic process consummating in health. The technics for determining quantitatively these chemical reactions and their interrelations with one another are for the most part undeveloped. Research directed toward the solution of any one disease offers an opportunity to study under optimal conditions relatively few of these chemical processes, and an understanding of the entire problem can be obtained only by making the most of every single opportunity for fundamental investigation. The solution of many seemingly unrelated problems undoubtedly depends on the same basic knowledge, and any investigation which utilizes the processes of only one disease offers little opportunity to solve this problem. It is imperative that investigators in each disease be provided with every opportunity to exploit to the fullest extent the opportunities to contribute to fundamental knowledge which are inherent in that disease problem.

120 Broadway.

Accidents Are Less Expensive in Older Workers.—The belief that the older worker is more of an accident risk than the younger worker is not justified by facts. Kossoris has shown that in 26,000 employees in four plants the accident rate was highest for the younger workers in terms of frequency rates. That is, the average number of disabling injuries per million workers was higher among young workers than among old. Men between the ages of 40 and 54 had rates only about two-thirds as high as workers under 21, and 70 per cent as high as those in their twenties. The rate for workers aged 60 and over was lower than for those under 21 and about the same as for those between 21 and 29 years of age. . . . There are some exceptions to the general rule that older workers are less prone to accidents. One of these is connected with working in high environmental temperatures. In a study of the incidence of accidents among coal miners reported by Vernon and Bedford it was found that, the higher the temperature, the greater was the rise in accidents among older workers as compared with younger ones. Although usually older workers tend to be involved in few accidents, the duration of each disability tends to increase. Their injuries are apt to be more severe, and the healing process is slower. . . . The diminished accident rate for older workers more than counterbalances this longer healing period so that, in general, it may be concluded that older men have proved less expensive from the standpoint of accident cost than younger men.—Shock, N. W.: Older People and Their Potentialities for Gainful Employment, *J. Gerontology,* April 1947.

SUSTAINED HYPERTENSION

Predisposing Factors and Causes of Disability and Death

ROBERT L. LEVY, M.D.
New York
PAUL D. WHITE, M.D.
Boston
WILLIAM D. STROUD, M.D.
Philadelphia
and
BRIGADIER GENERAL CHARLES C. HILLMAN
United States Army (Retired)
Miami, Fla.

In previous publications[1] statistical analyses have been made to indicate the prognostic significance of transient hypertension, transient tachycardia and overweight. It has been shown that the presence of each of these three conditions, by itself, increases the probability of the later development of sustained hypertension and of retirement or death with cardiovascular-renal disease. The presence of two of these conditions is of greater importance in this respect than that of any one alone. The presence of all three is a circumstance of major prognostic importance.

The present study is intended to integrate the earlier reports. Because of the relatively small number of men who died during the periods of observation, retirements for disability and deaths have now been grouped together as medical casualties in service. In addition, the frequency of the primary causes of retirement and death have been tabulated for the cases with sustained hypertension. And finally, conclusions have been drawn which, it is hoped, will prove useful in formulating revised criteria for the selection of those physically qualified for military service.

MATERIAL, CRITERIA AND METHOD

The same medical records of 22,741 army officers which served as the source of material for earlier papers in the series were used in this investigation. The manner of collecting and analyzing the data has been described in previous publications.[1]

By sustained hypertension was meant a reading of over 150 mm. of mercury systolic or 90 diastolic, persisting throughout one examination and not followed in subsequent examinations by levels lower than these. Transient hypertension was taken to mean a reading above these same levels but which was followed on any particular examination or at a later examination by a reading below these levels. By transient tachycardia was meant a heart rate of 100 per minute or over, of sinus origin, which was followed after rest on any particular examination by a rate under 100. An officer was considered to be overweight if he was heavier, by 20 pounds (9 Kg.) or more, than the standard given in Army Regulations 40-105, issued by the War Department on Oct. 15, 1942.[1e] These standards were calculated according to height and age. The 20 pound (9 Kg.) excess as a criterion of obesity was chosen arbitrarily and without regard for the acceptable minimum and maximum weights included in the original army table. The age was noted at which overweight was first observed, and from then on the person was placed in the overweight class.

Cardiovascular-renal conditions, if present, were always included in the tabulation as causes of retirement or death, even though not recorded as directly responsible for either. Thus an officer may have retired or died with such a disorder but not necessarily because of it.

As in the papers to which reference already has been made, the method of person-years, specific for age, was employed in the analysis in order to obtain the proper base from which to calculate the various rates on the usual annual basis.

TABLE 1.—*Later Occurrence of Sustained Hypertension, by Age, Among 22,741 Army Officers*

Age	Person-Years Observed	Number Developing Sustained Hypertension	Rate per 1,000
25-29	33,199	19	0.6
30-34	39,071	41	1.0
35-39	42,479	100	2.4
40-44	41,300	191	4.6
45-49	34,091	365	10.7
50-54	21,954	406	18.5
55-59	11,776	350	29.7
Total	223,870	1,472	6.6

FACTORS INFLUENCING THE LATER DEVELOPMENT OF SUSTAINED HYPERTENSION

Transient Hypertension and Transient Tachycardia.—There were, among the 22,741 officers, 223,870 person-years of observation, indicating an average follow-up of 9.8 years. In table 1 are given the rates of developing sustained hypertension at the various ages, for the entire experience. Of the total, 176,410 person-years pertained to the group without transient hypertension. In 550 persons of this group sustained hypertension developed, giving a rate of 3.1 per thousand. Among the remaining 47,460 person-years for the group with transient hypertension, there were 922 cases with later sustained hypertension, or a rate of 19.4 per thousand. However, this latter group is loaded for the older ages so that, after adjusting for this fact, the rate becomes only 11.3 per thousand. Thus, the rate of the later development of sustained hypertension is 3.6 times as high in the group with transient hypertension as in the group without it.

It has already been shown[1c] that, with respect to the later development of sustained hypertension, all levels of transient hypertension, both systolic and diastolic, are significant. Of particular interest was the observation that slight degrees of elevation are important, even when the systolic level alone is involved. Of the greatest prognostic significance, however, is a transient rise in diastolic pressure above 100 mm. of mercury.

Dr. John W. Fertig, professor of biostatistics, Columbia University College of Physicians and Surgeons, aided in the analysis and preparation of the material for final presentation.

This is the sixth and final paper in a series dealing with "Studies of Blood Pressure in Army Officers." The six papers will be printed together as a pamphlet, copies of which may be obtained from the authors.

The work described in this paper was begun under a contract, recommended by the Committee on Medical Research, between the Office of Scientific Research and Development and Columbia University. The contract was transferred on Nov. 1, 1945 from the Office of Scientific Research and Development to the Army Research and Development Board, Office of the Surgeon General.

When transient tachycardia is present as well as transient hypertension, the picture is even more specific. Among the 165,216 person-years in which neither condition was present, there were 409 cases of later sustained hypertension, giving a rate of 2.5 per thousand. The rates for the groups in which only one of these two conditions was present were 3.4 times as large in both instances, after due allowance was made for the differences in the age distributions. When both conditions were present, the rate for the later development of sustained hypertension was 7.5 times as large as when both were absent.

TABLE 2.—*Later Occurrence of Sustained Hypertension, by Age, for Experience Without Transient Hypertension, Transient Tachycardia or Overweight*

Age	Person-Years Observed	Number Developing Sustained Hypertension	Rate per 1,000
25-29	25,339	8	0.3
30-34	26,926	10	0.4
35-39	26,269	28	1.1
40-44	22,562	32	1.4
45-49	16,650	65	3.9
50-54	9,681	53	5.5
55-59	4,542	48	10.6
Total	131,969	244	1.8

Overweight.—When something is known about the status of the person with respect to overweight, the situation is greatly altered. In table 1 are given the rates of development of sustained hypertension for the entire experience. In table 2, by way of contrast, are given the rates for the 131,969 person-years when transient hypertension, transient tachycardia and overweight were absent. There were 244 cases in this group, giving a rate of 1.8 per thousand. When adjusted to the age distribution of table 1, the rate becomes 2.3 per thousand. This is only about one third as high as the rate of 6.6 for the whole experience in which the various factors are mixed together, with one or another present or absent in different portions.

There are eight possible combinations of overweight, transient hypertension and transient tachycardia. These have not all been studied because of the complicated processes of tabulation involved and also because the number of person-years in some groups would be exceedingly small. The important relationships with regard to overweight have already been demonstrated.[1e] When overweight alone was present the rates were, on the average, 2.5 times as large as those of table 2, in which none of the three factors was present. When overweight was absent but both other factors were present the rates were, on the average, 8.7 times as large as those of table 2. Finally, when all three factors were present the rates were 12.3 times as large. All these differences are significant, indicating that the presence of overweight, regardless of the presence or absence of the other two factors, increases the risk of the later development of sustained hypertension.

CASUALTY RATES

In preceding papers disability retirements and deaths have been considered separately. In the discussion which follows, these categories have been combined as casualties because they represent, together, the total loss of manpower to the service and also because of the comparatively small number of deaths which occurred during the periods of observation. The low death rate was due to care in initial selection as well as to prompt retirement when disability rendered the officer unfit for active duty.

In table 3 are given the casualty rates among the 22,741 men. These may be summarized conveniently by actuarial methods. They imply that of 1,000 officers at age 25, 509 would survive to age 60 while 491 would be casualties by that age. Of the 491 casualties, 218 would be associated with cardiovascular-renal diseases and 273 with other conditions.

Regardless of other factors, the casualty rates for cardiovascular-renal diseases are significantly higher for the group with transient hypertension than for the group without it. On the average, the rate is twice as great. The casualty rates for non-cardiovascular-renal diseases also tend to be a little higher at most ages when transient hypertension is present than when it is obsent. While the rate is only 20 per cent larger, on the average, this is statistically significant.

Analysis of the relative importance of various levels of transient hypertension in relation to the casualty rates with cardiovascular-renal diseases shows the same trends as were noted for the later development of sustained hypertension, and as were noted for retirements and deaths separately.[1c] Here again, with one possible exception, every transient elevation above the normal, for both systolic and diastolic pressures, shows a statistically significant increase in the rate. Again, it is a diastolic reading of over 100 mm. of mercury which is of the greatest importance.

When transient tachycardia is present as well as transient hypertension, other interesting differences become apparent. The casualty rates for the cardiovascular-renal diseases when neither condition is present is 2.8. If transient hypertension alone is present, the rate is 1.9 times as large; if transient tachycardia is present alone, the rate is 1.8 times as large. If both transient hypertension and transient tachycardia are present, the rate is 2.9 times as large. All these differences are significant. The presence of either condition alone, therefore, has about the same effect in increasing the cardiovascular-renal casualty rate. The presence of both factors is of considerably greater importance in this respect. The effect on the rates for the non-cardiovascular-renal diseases is considerably less. The rate when neither condition is present is 7.7 per thousand. When transient tachycardia alone is present the rate is 70 per cent higher, but for the other two comparisons the rates are only some 20 per cent higher.

TABLE 3.—*Disability Retirements and Deaths, With and Without Cardiovascular-Renal Diseases, by Age, for 22,741 Officers*

		Casualties				
		Number		Rates per 1,000		
Age	Person-Years Observed	CV-R	Non-CV-R	CV-R	Non-CV-R	Total
25-29	33,241	12	246	0.4	7.4	7.8
30-34	39,176	15	282	0.4	7.2	7.6
35-39	42,747	46	324	1.1	7.6	8.7
40-44	41,892	124	377	3.0	9.0	12.0
45-49	35,180	250	367	7.0	10.4	17.5
50-54	23,298	406	292	17.4	12.5	30.0
55-59	13,022	477	190	36.6	14.6	51.2
Total	228,556	1,330	2,078	5.8	9.1	14.9

When overweight is taken into consideration, as well as transient hypertension and transient tachycardia, other differences appear. When all these factors are absent 132,923 person-years are involved, among which there are 324 casualties with cardiovascular-renal diseases and 984 with non-cardiovascular-renal diseases.

Table 4.—*Disability Retirements and Deaths, With and Without Cardiovascular-Renal Diseases, by Age, for Experience Without Transient Hypertension, Transient Tachycardia and Overweight*

		Casualties				
		Number		Rates per 1,000		
Age	Person-Years Observed	CV-R	Non-CV R	CV R	Non-CV-R	Total
25-29	25,356	8	174	0.3	6.9	7.2
30-34	26,957	7	167	0.3	6.2	6.5
35-39	26,342	10	157	0.4	6.0	6.3
40-44	22,765	29	169	1.3	7.4	8.7
45-49	16,885	68	146	4.0	8.6	12.7
50-54	9,924	93	99	9.4	10.0	19.4
55-59	4,751	109	72	22.9	15.2	38.1
Total	132,923	324	984	2.4	7.4	9.8
Adjusted to correspond to age distribution of person-years in table 3				3.2	7.8	11.0

The rates at the various ages are given in table 4. These may be contrasted with the rates for the total experience in table 3, in which the various factors are mixed together, with one or another absent in different portions. It is thus apparent that the cardiovascular-renal casualty rates at the various ages, shown in table 4, are approximately half as large as those for the total experience. The rates for non-cardiovascular-renal diseases also run somewhat lower. The casualty rates at all ages, as given in table 4, are not immediately comparable to the corresponding values of table 3 because of differences in the relative age distributions. After proper adjustment, the rates at all ages become 3.2 for cardiovascular-renal diseases, 7.8 for non-cardiovascular-renal diseases, and 11.0 for all causes, contrasted with the corresponding rates of 5.8, 9.1 and 14.9 for table 3.

The effect of overweight may also be noted by comparing the cardiovascular-renal and non-cardiovascular-renal casualty rates when only the factor of overweight is present, with those of table 4, when all the modifying factors are absent. On the average, the rate is 50 per cent larger for the cardiovascular-renal conditions and 20 per cent larger for the non-cardiovascular-renal conditions. The latter increase is, however, of doubtful significance. When transient hypertension, transient tachycardia and overweight are all present, the rates are 260 per cent larger and 40 per cent larger, respectively.

These comparisons may be restated as follows: Of 1,000 persons at age 25 without any of the three modifying factors present, 610 would survive to age 60 while 390 would be casualties; 140 would be casualties attributable to cardiovascular-renal diseases and 250 to non-cardiovascular-renal diseases. With overweight alone present, there would be 545 survivors to age 60 with 455 casualties, of which 178 would be associated with cardiovascular-renal diseases and 277 with other conditions. With transient hypertension, transient tachycardia and overweight all present, there would be only 344 survivors and 656 casualties, of which 370 would be cardiovascular-renal and 286 non-cardiovascular-renal.

It is thus clear that overweight alone is significant as a factor in increasing the casualty rate for cardiovascular-renal diseases. If combined with transient hypertension and transient tachycardia, it is followed by a rate almost four times as great as in the group in which none of these conditions is found. The effect of overweight is much less striking for the non-cardiovascular-renal diseases.

CASUALTIES AMONG CASES OF SUSTAINED HYPERTENSION

A review of the primary causes of retirement gives, of necessity, an incomplete picture of the late effects of hypertension because it can deal only with those which occur during the period of observation. Information concerning an officer's state of health after leaving the army is not contained in his file. After sustained hypertension was first discovered, the average duration of follow-up, in this series of cases, was only about three years. The number of men who died in service was comparatively small; most of those suffering from a chronic ailment were promptly retired and the causes of death are not known. The figures to be given, therefore, are not comparable to those appearing in other studies of hypertensive vascular disease in which the follow-up periods were longer. However, the recorded retirements and deaths, together, furnish data on total casualties while on active duty.

Among 22,741 officers, sustained hypertension developed in 1,472 (table 1). This is an incidence of 6.5 per cent. In table 5 are given the primary causes of retirement and death for the casualties in this group. There were in all 918 casualties, of which 741 retired and 177 died. The various causes are listed in the order of their frequency with respect to total casualties.

Table 5.—*Primary Causes of Retirement and Death in Group with Sustained Hypertension*

	Number		
Causes of Retirement and Death	Retired	Died	Total Casualties
Cardiovascular	534	96	630
Hypertension	318	0	318
Coronary heart disease (including angina pectoris and thrombosis)	80	47	127
Cerebral arteriosclerosis (including hemorrhage and thrombosis)	68	24	92
Valvular heart disease	21	0	21
Heart disease (type unspecified)	10	11	21
Congestive failure	7	11	18
Arteriosclerosis (generalized)	16	0	16
Cardiac arrhythmia	13	0	13
Aneurysm of aorta (ruptured or dissecting)	0	3	3
Dilatation of aorta	1	0	1
Renal	21	12	33
Chronic nephritis	17	9	26
Other	4	3	7
Miscellaneous	186	69	255
Total	741	177	918

Retirements.—Of 555 persons retired for cardiovascular-renal diseases, the most frequent primary cause of disability obviously was hypertension, which accounted for 318 cases. Next in order came coronary heart disease, with 80 cases; in 40 of these the patient experienced an attack of thrombosis. Cerebral arteriosclerosis was third on the list, with 68 cases; these included 17 cases of hemorrhage and 10 of thrombosis of cerebral vessels. These three conditions together were responsible for 84 per cent of all retirements for cardiovascular-renal diseases. Valvular heart disease, cardiac disease of unspecified type, congestive failure, generalized arteriosclerosis, cardiac arrhythmia and dilatation of the aorta each accounted for less than 22 cases.

In the renal group there were 21 cases, of which 17 were instances of chronic nephritis. Uremia was not noted.

There were 186 retirements for miscellaneous reasons, with neuropsychiatric conditions heading the list with 53 cases. Trauma, with 20, and arthritis, with 18, came next in order.

Deaths.—One hundred and eight officers with sustained hypertension died of cardiovascular-renal conditions while in service. Coronary heart disease caused death in 47; among these, thrombosis occurred in 39. Cerebral hemorrhage killed 24. These two conditions ogether accounted for 66 per cent of the 108 fatalities ue to cardiovascular-renal conditions. It is of interest that in not a single instance was valvular heart disease given as the primary cause of death. Cardiac disorders of unspecified type and congestive failure caused 11 deaths each. There were 3 cases of aortic aneurysm; 2 ruptured, and 1 was of the dissecting variety.

Among 12 renal deaths, 9 were due to chronic nephritis. Uremia occurred only once.

In the miscellaneous group malignant diseases headed the list, having caused death in 14 cases. Pneumonia and trauma each accounted for 11 deaths, and suicide for 9.

Total Casualties Due to Cardiovascular-Renal Diseases.—If retirements and deaths are combined, hypertension itself, coronary heart disease and cerebral vascular disorders were by far the leading causes of loss to the service of men with sustained hypertension. Together, they caused 81 per cent of the total number of casualties due to cardiovascular-renal conditions. Chronic nephritis was next in frequency. Of lesser importance were valvular heart disease, cardiac disease of unspecified type, congestive heart failure and generalized arteriosclerosis.

Among the miscellaneous causes, in order of frequency, were neuropsychiatric conditions, trauma, arthritis, gastrointestinal disorders and malignant disease.

SUMMARY AND CONCLUSIONS

1. Statistical analyses were made of the medical records of 22,741 officers of the United States Army to determine the prognostic significance of transient hypertension, transient tachycardia and overweight noted in the course of annual physical examinations. The method of person-years was employed in the analyses.

2. The indexes chosen to demonstrate the influence of these three factors on the subsequent state of health and cause of death were the rates of the later development of sustained hypertension and of retirement or death with cardiovascular-renal diseases.

3. Transient hypertension or transient tachycardia or overweight, each by itself, increased the probability of the later development of sustained hypertension and of retirement or death with cardiovascular-renal disease. The presence of two of these conditions was of greater importance, in these respects, than that of any one alone. The presence of all three was a circumstance of major prognostic importance.

4. In the group in which sustained hypertension developed, the leading causes of retirement because of cardiovascular-renal diseases were hypertension itself, coronary heart disease and cerebral arteriosclerosis, including hemorrhage and thrombosis. These three conditions together accounted for 84 per cent of such retirements. Coronary heart disease and cerebral hemorrhage together were responsible for 66 per cent of the deaths from cardiovascular-renal conditions during the period of observation.

5. In revising standards for the selection of those physically qualified for military service, factors predisposing to the later development of sustained hypertension and cardiovascular-renal diseases should be taken into account. When making disposition of men in whom sustained hypertension develops while they are in service, consideration may well be given to the high incidence and disabling nature of the circulatory and renal complications associated with this condition. The extent to which the conclusions derived from these studies are applied can be varied according to the need for manpower.

6. It seems probable that the facts obtained from the analyses of the records of army officers hold true also for the general male population of comparable physical fitness and similar age groups.

POSTOPERATIVE RESULTS IN PRIMARY TENDON SUTURE OF THE HAND AND WRIST

MARK B. COVENTRY, M.D.
and
NORMAN R. BECK, M.D.
Rochester, Minn.

Successful repair of the severed tendon is a problem which has not been completely solved. Numerous excellent articles on the subject have appeared in recent years,[1] but certain factors still prevent the surgeon from achieving the best result in the surgical repair of a lacerated tendon, especially of the hand and wrist.

In the period from Jan. 1, 1935 to Jan. 1, 1945 primary suture of the tendons of the hand and wrist was performed at the Mayo Clinic in 43 cases. Only the cases in which the patients were treated within four hours after injury and in which bone was not involved were included. Cases of secondary repair and tendon grafts were excluded from the group. Tendon lacerations, compound fractures and avulsions are encountered fairly commonly in the same case at the clinic because of the accidents which occur in the large surrounding rural community. In the fall accidents with corn shredders and other farm machinery occur frequently. Fortunately, the number of these accidents is diminishing, due in no small part to the publicity

---

given them at farmers' meetings. Young has been especially active in this regard.[2]

The average time which elapsed from injury to repair was one hour and forty-two minutes. This was a favorable factor. The incidence of infection was low: in 12 cases slight drainage occurred about the suture, and in only 2 cases was frank infection present. With the present availability of chemotherapeutic agents the incidence of infection may be expected to fall even lower.

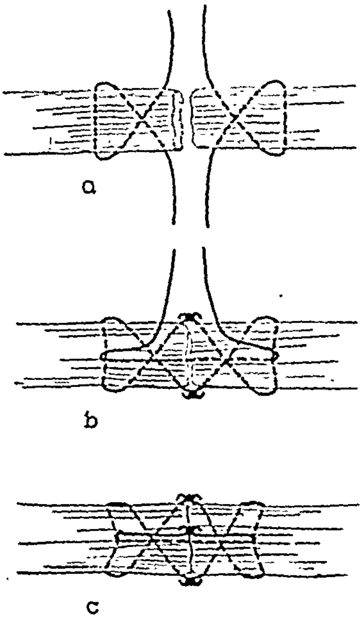

Fig. 1.—Method of suturing tendon. In *b* and *c* the usual method is modified. A "stay" suture is used for additional strength and closer approximation.

Almost all suture material used during this ten year period was silk. Since Bunnell's[1a] report of his work we have used stainless steel wire sutures, as well as silk, with gratifying results. In most cases we prefer to bury the suture. The technic of suture varies, but the method shown in the accompanying illustration has been found satisfactory. The actual technic is difficult to evaluate because the injuries have been repaired by several different surgeons. Excellent articles covering surgical principles and technic have been published by Mason[1c] and by Koch.[1b]

The following rules are important: 1. Thorough toilet of the wound should be carried out. 2. Tissues should be handled carefully. 3. Hemostasis should be complete. 4. Incisions should be made in the creases. 5. A minimal number of sutures and small knots should be used. 6. The fibrous tendinous sheath should be removed, and fat should be placed in apposition over tendons. 7. Tendons of the flexor digitorum sublimis should be removed or allowed to retract; only tendons of the flexor digitorum profundus should be sutured when the two are severed. 8. Splints should be used, and physical therapy should be given.

The question of whether splints should be used is somewhat controversial. No deductions can be made from the cases reported herein. All tendons were splinted for varying periods. Bunnell recommended early motion after repair to prevent adhesions. Koch and Mason advocated splinting for three or four weeks to prevent adhesions. We think that splinting of the tendons of the flexor muscles for four weeks and of tendons of the extensor muscles for six weeks is ideal. The splint should be removed as soon as possible (in a few days if integrity of the suture is adequate, in ten or twelve days if it is doubtful) and the tendon should be passed through a full range of active motion once a day. Excessive motion during this healing stage may increase adhesions.

Excellent results were those in which there was no disability and the patient had no complaints. Good results were those in which 75 per cent or more of normal function was obtained, but the result was short of perfect. Poor results were those in which less than 75 per cent of normal function was restored. Cases involving the tendons of the extensor muscles are grouped together, for the problem is essentially the same whether they are severed at the wrist, metacarpal region or fingers. Results were poorest in cases of injury of the tendon of the flexor muscle when the injury was in a region where a fibrous tendinous sheath exists, as in the finger or under the transverse carpal ligament, which is essentially a fibrous tendinous sheath. Results for the two groups are presented in the accompanying table. In the 3 cases of severed tendons of the flexor muscles of the fingers and palm in which the results were classed as poor, a second operation was performed later and results were good. In 1 case the suture pulled out after the first operation; in the other 2, poor results were due to adhesions and later transplantation of tendons was performed with a good outcome.

ANALYSIS OF THE POOR RESULTS

I. *Tendons of the Flexor Muscles in the Fingers and Palm*

CASE 1.—*Tendon from the flexor digitorum profundus to the forefinger.* The tendon was badly contused and lacerated by an electric fan. Primary suture was not done. Because the distal phalanx ultimately became stiff and without sensation, amputation of the distal phalanx was performed.

CASE 2.—*Tendons from the flexor digitorum profundus and flexor digitorum sublimis to the index finger.* The tendons were lacerated by a buzz saw. The distal interphalangeal joint was not movable; the proximal interphalangeal joint could be flexed only to 30 degrees. The tendons of the flexor digitorum profundus had become adherent to the tendons of the flexor digitorum sublimis. Secondary repair was advised, but the patient refused surgical treatment.

CASE 3.—*Tendon of the flexor pollicis longus.* After a buzz saw caused injury to the tendon at the base of the proximal phalanx of the thumb slight purulent drainage occurred for two weeks. As a final result the distal phalanx could not be flexed but was stable in a neutral position.

CASE 4.—*Tendons from the flexor digitorum profundus and flexor digitorum sublimis to the index finger.* In spite of warnings by physicians[3] injuries on broken porcelain handles of water faucets still occur. This patient severed the tendons from the flexor muscles to the index finger at the metacarpophalangeal joint on the broken handle of a faucet. End to end suture of both tendons was performed, and infection did not occur; but as a result only half normal flexion of the distal and middle phalangeal joints could be accomplished. However, the patient is able to type.

[3] Steenrod, E. J.; Ghormley, R. K., and Craig, W. McK.: Injuries of the Hands Due to Shattered Porcelain Handles of Water Faucets, Surg., Gynec. & Obst. **64**: 950-955 (May) 1937.

Case 5.—*Tendons from the flexor digitorum sublimis and flexor digitorum profundus to the index finger.* The tendons were severed at the metacarpophalangeal joint on the porcelain handle of a water faucet. Silk sutures pulled out, and repair was made again one month later. The result of the secondary repair was classified as good (more than 75 per cent of normal function in the finger).

Case 6.—*Tendons from the flexor digitorum sublimis and flexor digitorum profundus to the ring finger.* The tendons were lacerated by a power mower. Infection occurred, and the tendon sloughed at the proximal interphalangeal joint. A tendon was transplanted subsequently. The tendon of the extensor muscle of the fourth toe was used. The result was classed as good after the secondary procedure.

Case 7.—*Tendon of the flexor pollicis longus.* The tendon was lacerated on a broken cup. Adhesions occurred, and as a result the distal phalanx could not be flexed. However, the joint was stable.

Case 8.—*Tendons from the flexor digitorum sublimis and flexor digitorum profundus to the ring finger.* This laceration occurred at the metacarpophalangeal joint when the patient, a boy 2 years of age, fell on some glass. The original repair of the tendon to the fourth finger was successful. The little er failed to function after the first repair. Another opera- n was performed, but no appreciable improvement in flexion sulted.

II. *Tendons of the Flexor Muscles at the Wrist*

Case 9.—This patient fell through a window and all tendons of the flexor muscles, nerves and radial and ulnar arteries at the wrist were lacerated. The arterial lacerations were not complete and some circulation persisted, but an arteriogram later showed terminal occlusion of all digital arteries without adequate collateral circulation. The poor result cannot be attributed entirely to the injury to the tendons.

III. *Tendons of the Extensor Muscles*

Case 10.—*Tendons from the extensor digitorum communis to the fourth and fifth fingers.* Laceration occurred while the patient was chopping wood with an ax. The injury was located 5 inches (12.7 cm.) above the wrist. Splinting was carried on for sixty days after suture of the tendons with silk. When the patient was last examined, nine years after the injury, full extension of the fingers was possible when the wrist was held in a neutral position, but the fingers could not be fully extended when the wrist was dorsiflexed. The patient did not consider that he was handicapped for general labor.

Case 11.—*Tendon from the extensor digitorum communis to the index finger.* The tendon was lacerated at the proximal interphalangeal joint. After repair of the injury with silk sutures, seropurulent drainage occurred. On last examination the joints of the distal and middle phalanges were practically immovable.

SUMMARY

The postoperative results of suture of acute lacerations of the tendons of the hand and wrist encountered at the Mayo Clinic in a ten year period have been reported. Poorest results were obtained when lacerations of the tendons of the flexor muscles occurred at the finger through the fibrous tendinous sheath. Careful adherence to the rules presented gives a higher percentage of good results. Two or more surgical procedures are necessary in many cases before all that can be done for the patient is accomplished. The poor results have been evaluated carefully. In some cases they were due to infection; in others, to suture of the tendon of the flexor digitorum sublimis as well as the tendon of the flexor digitorum profundus. In 1 case poor results were due to prolonged splinting. In some of the cases in which the results were classed as poor there seemed to be factors which were beyond control.

POLYETHYLENE, A NEW SYNTHETIC PLASTIC FOR USE IN SURGERY

Experimental Applications in Neurosurgery

FRANC D. INGRAHAM, M.D.
EBEN ALEXANDER Jr., M.D.
and
DONALD D. MATSON, M.D.
Boston

The synthetic plastics industry has contributed a large number of materials that have been used in making diagnostic and therapeutic instruments. The number of synthetic plastics that can be buried safely within human tissues, however, is surprisingly small. Methyl methacrylate ("lucite," "plexiglas," "perspex") and nylon have been found, after extensive animal experimentation and clinical use, to be well tolerated by tissues.[1] Methyl methacrylate is a hard, transparent plastic suitable for cranioplasty, dentures, soft tissue prostheses in plastic surgery, rigid tubes and other uses not requiring pliability. Nylon is well known as a suture material. Many other plastics have been used sporadically in clinical surgical practice but discarded for various reasons.

There is need for a synthetic plastic material of pure composition, well tolerated by tissues, which can be made into flexible tubes and thin, pliable sheets. A relatively new plastic material, polyethylene [1a] ("polythene"), has been found to fill these needs. The subsequent discussion will deal with a description of polyethylene and the presentation of experimental data.

✓ DESCRIPTION OF POLYETHYLENE

Polyethylene is a long-chained polymer of ethylene and has, on theoretic grounds, the simplest chemical formula of all the plastics.[1b] Each molecule is formed of a saturated aliphatic hydrocarbon chain, each carbon atom of which carries two hydrogen atoms:

$$\left(-\overset{\text{H}}{\underset{\text{H}}{\text{C}}}-\right)_n$$

Bailey [2] has stated that each molecule contains 200 to 1,000 or more ethylene units. As it is now manufactured, polyethylene has a molecular weight of about 18,000, which is suitable for extrusion into tubes and thin sheets.

Polyethylene was first produced in 1936, when a new process involving polymerization of ethylene under extremely high pressures was developed in Great Britain.[3] Somewhat later commercial production was begun, and the material was used extensively in the manufacture of airplanes as an electric wire insulator. The production of polyethylene was begun in the United States in 1943.

[3] Plastics Educational Booklet, American Association of School Administrators, Nov. 1, 1945. Prepared by Committee of Delaware Members. H. V. Holloway, State Superintendent of Schools, Delaware, Chairman.

This plastic has a microcrystalline structure; it is not completely transparent, but has a slightly cloudy appearance. It is a decidedly tough thermoplastic resin which, unlike most plastic materials, does not require the addition of another chemical compound to make it flexible and pliable. Such chemicals, called plasticizers, are frequently added to plastic materials to increase their pliability, but plasticizers are generally tissue irritants. In thin sections polyethylene is extremely flexible, but it does not have the limp, rubbery quality characteristic of most nonrigid plastics. It has been used extensively in industry because of its electrical insulating properties. To enhance these properties substances called antioxidants are sometimes added. These added substances, the exact nature of which is not divulged by the manufacturers, are considered to be as harmful to tissues as plasticizers, and only the pure polyethylene should be used in surgical practice. A more complete discussion of this aspect of synthetic plastics may be found elsewhere.[1]

Polyethylene will stretch without breaking easily, but it has relatively little elasticity It is light, with a specific gravity of 0.92. Water absorption is slight; the material is unaffected by salt water. It is chemically inert and is resistant to most of the common solvents. It is not affected at room temperatures by such compounds as concentrated hydrochloric, sulfuric or hydrofluoric acids. Concentrated sodium hydroxide does not alter the plastic. Carbon tetrachloride and trichloro-ethylene cause the plastic to swell at room temperature but do not dissolve it

Polyethylene becomes amorphous above 115 C., but its physical properties are not significantly altered by ordinary climatic temperatures or by the range of body temperature changes. It remains flexible and strong over a wide range of temperature changes.

Because of its low melting point, polyethylene is reduced to an amorphous mass by autoclaving. Boiling it in water does not seem to change its physical properties significantly, except that it retains the shape in which it is placed during boiling. Sterilization of the plastic by soaking it in a 1 : 1,000 aqueous solution of benzalkonium chloride ("zephiran chloride" N. N. R.) for eighteen to twenty-four hours has proved satisfactory, and this method has been used in the experiments reported herein. Since the plastic, either in the form of a tube or a film, is lighter than water, it must be weighted to the bottom of the solution in which it is sterilized, and care must be taken to insure contact between the sterilizing solution and the lumen of the tube, particularly tubes of small caliber.

Polyethylene can be extruded easily in the form of tubes of any convenient size or in sheets of any desirable thickness. Tubes with an outside diameter of 1 mm. and film 0.002 inch (0.005 cm.) thick have been found easy to handle and suitable for surgical procedures (fig. 1). In the form of either tube or film the plastic is inexpensive.

REVIEW OF THE LITERATURE

There have not been any published reports of controlled tissue experiments with polyethylene. Meyers[4] described a method of intravenous catherization using a tubing known as "med-o-seal."[5] Material for this use has been supplied to this laboratory as polyethylene. His paper does not state whether the tubing he actually used was polyethylene or some other plastic material. He reported that the plastic he used produced no foreign body reaction in human tissues; he reported no animal experimentation.

Poppe and De Oliveira[6] investigated methods of obliterating aneurysms by inducing fibrosis around them with irritating plastic film. They used a material called "polythene cellophane," which caused a pronounced fibrous reaction around the aorta in experimental animals. They used the same material in 4 human cases but without sufficiently long follow-up to report results. The exact type of polyethylene used was not recorded.

Diamond and Thomas[7] have used small caliber polyethylene tubing in the treatment of newborn babies with erythroblastosis. They have inserted the tubing through the umbilical vein into the inferior vena cava, leaving the tube in place up to three hours. Through the tubing 450 cc. of the blood of the infant has been withdrawn and replaced by 500 cc. or more of Rh negative blood. No evidence of irritation from the tubing has been seen, and the infants treated in this way have shown immediate improvement.

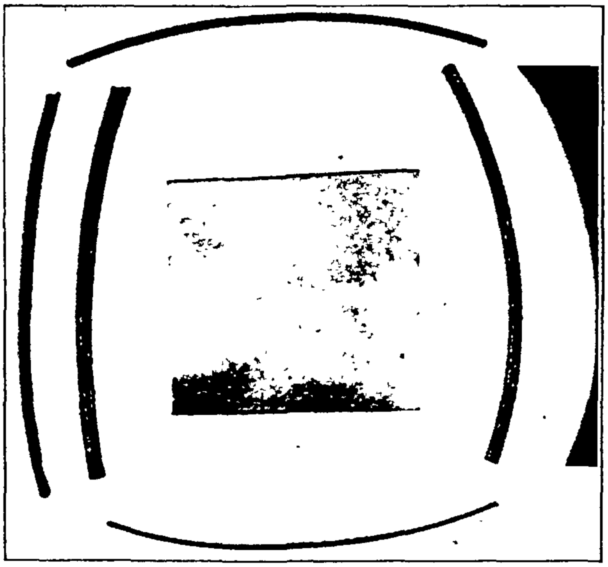

Fig. 1.—Samples of pure polyethylene film and hollow tubing. On the extreme left and the extreme right of the figure are sections of no. 8 F soft rubber catheter for comparison of size. The film is 0.002 inch (0.005 cm.) thick. The tubing can be extruded in any diameter desired.

EXPERIMENTAL DATA

Scope of the Investigation.—Interest in the present investigation was focused principally on the reactions produced by this plastic in the central nervous system and its coverings. Two general groups of experiments were therefore undertaken: (1) implantation of polyethylene directly into the cerebral cortex, and (2) replacement of an area of excised dura with polyethylene film. The experiments were controlled by the performance of similar operative procedures without use of the plastic on the contralateral side in the same animal.

Tissue reactions were studied in 43 cats, 10 dogs, 9 monkeys and 3 rabbits. The animals were killed at scheduled intervals of 5, 7, 10, 14, 21, 30, 60, 90 and 150 days after operation. When animals died of some condition not related to the experiments, they were included in this study only if they were free from infection in or near the operative site. None of the animals showed evidence during life of cerebral irritation or of any unusual behavior that could be attributed to the presence of polyethylene.

[7] Diamond, L. K., and Thomas, W. O., Jr.: Replacement Transfusions in the Treatment of Severe Erythroblastosis Fetalis by a Single Plastic Catheter in the Umbilical Vein, to be published.

The animals were killed with an overdose of pentobarbital sodium, the carotid arteries perfused with isotonic solution of sodium chloride followed by 10 per cent solution of formaldehyde; the brains were removed intact and placed in 10 per cent solution of formaldehyde for further fixation. Microscopic sections stained with hematoxylin and eosin were then prepared for detailed study of the histologic responses to the presence of the plastic.

I. *Implantation of Polyethylene into the Brain.*

Segments of polyethylene tubing 3 to 5 mm. in length with an outside diameter of slightly more than 1 mm. were embedded in the parietal lobe of the cerebral hemisphere. This was accomplished through a tiny lural flap exposed through a small bur hole. The ubing, beveled at one end, was introduced into the cerebral tissue perpendicular to the surface. The operative wounds were closed in layers with silk. Similar experiments were performed with polyethylene film wrapped tightly in the form of a cylinder and embedded in the brain perpendicular to the cortex.

At the time these animals were killed the local site of implantation was carefully examined. In none of them was there evidence of any gross reaction around the polyethylene. Both the tubing and the film could be slipped easily out of the location in the cerebral tissue, leaving a discrete round hole without gross distortion of the surrounding tissue.

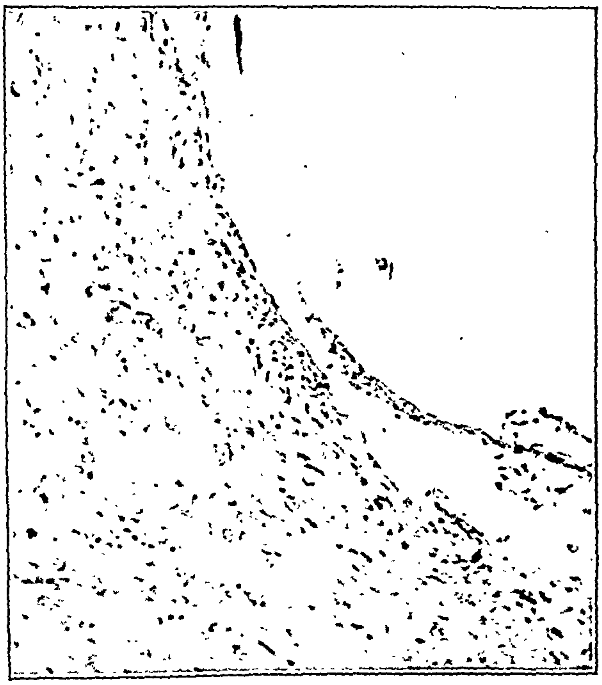

Fig. 2 (cat 64).—Photomicrograph of cerebral cortex seven days after implantation of polyethylene tubing (hematoxylin and eosin). Note the absence of polymorphonuclear leukocytes or increased vascularity. There is minimal small round cell infiltration, similar to that seen adjacent to a simple stab wound.

Histologic sections through the area of implantation up to ten days showed no more tissue reaction than was found adjacent to a control stab wound elsewhere in the cortex (fig. 2). No collections of polymorphonuclear leukocytes were found in any of the sections. Sections made through implantation sites in experiments lasting more than ten days showed a thin layer of glial tissue and slightly compressed cerebral tissue around the cavity containing the plastic. The glial layer was one to three cells in thickness and increased gradually over the weeks, until at ninety days it was six to eight cells thick. The surrounding cerebral tissue showed no increased vascularity and no inflammatory or foreign body reaction (fig. 3). The thin glial tissue lining the cavity was similar to that seen in response to tantalum, vitallium and methyl methacrylate, all of which have been established as well tolerated by human tissues.[8]

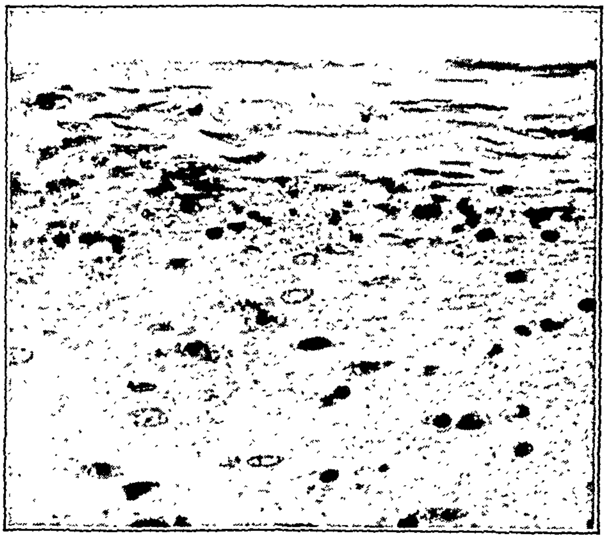

Fig. 3 (cat 66).—High power photomicrograph of the implantation site of polyethylene tubing, which had been placed in the cerebral cortex sixty-five days previously (hematoxylin and eosin). Note the increased thickness of the layer of glial tissue adjacent to the location of the tube. Also note the lack of increased vascularity and the minimal round cell infiltration.

In contrast to polyethylene, brains were examined in which du Pont "Cellophane (PT 300)" had been implanted in a similar manner.[9] The "Cellophane" was adherent to the surrounding tissue and could not be dislodged easily from its bed; there was edema around the implantation site early, with polymorphonuclear leukocytic infiltration. When the acute inflammatory response subsided after ten to twenty days an intense gliosis was evident, which became increasingly dense (fig. 4).

II. *Polyethylene Film Used as Dural Substitute.*

Thirty-two cats were subjected to operations in which polyethylene film 0.002 inch (0.005 cm.) in thickness was used to replace dura. In some instances bone flaps were elevated and replaced; in others a bone defect was created to expose the dura and was covered subsequently only by normal muscle. Difficulty was at first encountered in obtaining the film as pure polyethylene. Film containing antioxidants cannot always be differentiated grossly from pure film, and although it cannot be proved that the material used in early experiments was impure, it was observed that when material known to be pure was obtained the experimental results were much more satisfactory.

[8] Mackenzie, C. M.; Sharpless, D. H., and Millard, P.: Tissue Reactions to Vitallium and Acrylic Implants, Northwest Med. 44:277-283, 1945.

[9] Page, I. H.: A Method for Producing Persistent Hypertension by Cellophane, Science 89:273-274, 1939.

In earlier experiments, in which film of apparently impure quality was used, in several animals there developed relatively large hematomas between the arachnoid and the film. These were gradually absorbed and replaced by fibrous tissue. In the last 13 cats operated on, pure film was used and no hematomas were encountered except in 1 cat, in which a small hematoma formed under the anterior portion of the film. This development was also observed in 1 monkey, in which a piece of film 4 by 2 cm. was used to cover a large portion of one cerebral hemisphere. The collection of blood under the film measured 1 to 2 mm. in thickness and 1.5 cm. in width. This was not considered significant in view of its small size and the fact that the remainder of the cortex under the film was free of hemorrhage or gross reaction. In this case the presence of the hematoma was attributed to a technical error.

Animals killed in less than ten days showed *no gross* or microscopic reaction around the film, and the underlying cortex was plainly visible through it (fig. 5). After ten days, it became apparent that the film was being gradually encapsulated by a thin neomembrane on both its inner and outer surfaces. These layers were apparently derived from the dura. The inner surface was generally adherent to the underlying arachnoid by filmy adhesions; these were most pronounced immediately under the silk or nylon sutures used to attach the film to the dural edges. In animals that were allowed to survive thirty to ninety days, the film was found completely enclosed by a thin nonadherent fibrous envelope, or neomembrane, which contained a minute amount of clear fluid similar to that described in experiments with methyl methacrylate by Beck, Russell, Small and Graham[10] and to that found around thin tantalum foil by Pudenz and Odom.[11]

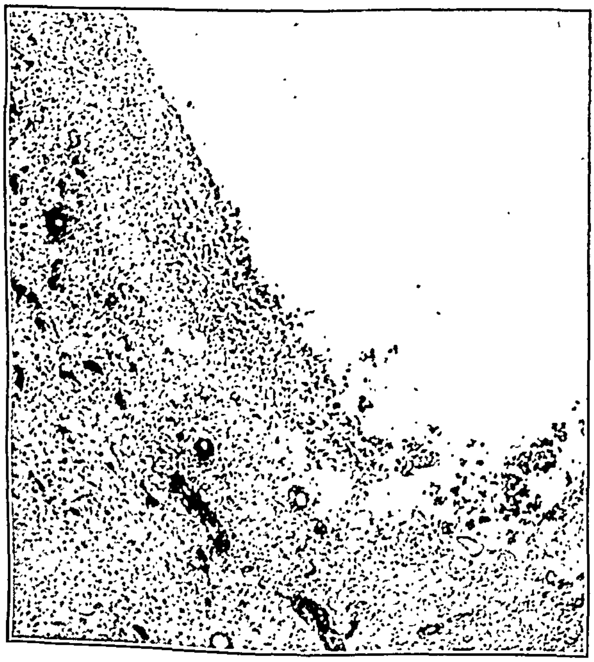

Fig. 4 (cat 74).—Low power photomicrograph of the implantation site of "Cellophane (PT 300)" five days after its introduction into the cerebral cortex (hematoxylin and eosin). Note the widespread infiltration of polymorphonuclear leukocytes and the perivascular cuffs of inflammatory cells. (Compare with *fig. 2.*)

The underlying cortex showed no abnormalities. There was mild thickening of the arachnoid, and in the early stages microscopic collections of red blood cells in the subarachnoid space, doubtless the result of operative trauma, were sometimes in evidence.

In 11 cats fibrin film was used as a dural substitute over the left cerebral hemisphere, polyethylene film over the right hemisphere. The use of fibrin film as a dural substitute is well known.[12] The degree of reaction to each type of film was about equal. Although the reaction to both polyethylene and fibrin film was found to be slight, in no instance was the cortex underlying the film as free of adhesions as was that under control dural flaps which had been raised and immediately resutured. Occasionally in animals killed up to thirty days, minute collections of fluid could be detected around both dural substitutes. None of the animals killed after the thirty day period showed any such formation of fluid.

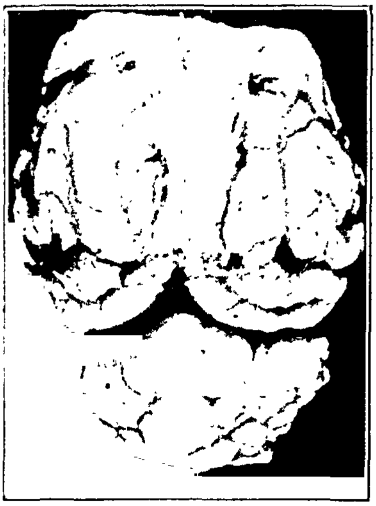

Fig. 5 (cat 95).—Postmortem photograph of polyethylene film which had been in place over the cerebral cortex for six days. Note the lack of gross reaction and the clear visibility of the underlying cortex through the film.

In 3 animals polyethylene was placed over damaged cortex replacing the dura. In 1 of these the cortex was damaged by removal of a piece of tantalum screen, which had been in contact with the cortex for one year and had become grossly adherent to it. This animal was killed twenty-one days after the film had been put in place. In the other 2 animals transcortical explorations of the lateral ventricles had been performed. The operative wound was reexplored after three days in 1 animal and after twenty days in the other. There was no gross reaction to the film in the animal explored after three days, and the presence of the artificial dural covering facilitated the reexploration. In the animals studied twenty days after operation there were adhesions to the neomembrane enclosing the polyethylene film similar to those found beneath normal dura in such circumstances.

Systematic experiments have not been performed to determine the effectiveness of polyethylene film in preventing meningocerebral adhesions over damaged cortex. The tissue response to this plastic is comparable to that observed by Pudenz and Odom[11] to thin tantalum foil. They noted that tantalum foil became encapsulated by a thin fibrous envelope, the under surface of which was adherent to the cortical cicatrix. They did not consider tantalum ideal for the prevention of meningocerebral adhesions; Delarue, Linell and McKenzie[13] have considered tantalum foil unsuitable for this purpose. It is likely that polyethylene film would behave in a similar manner, and a few preliminary experiments have substantiated this view. Further investigation of polyethylene over traumatized cerebral cortex is now being undertaken.

[12] Ingraham, F. D., and Bailey, O. T.: The Use of Products Prepared from Human Fibrinogen and Human Thrombin in Neurosurgery: Fibrin Foams as Hemostatic Agents; Fibrin Films in Repair of Dural Defects and in *Prevention of Meningocerebral Adhesions,* J. Neurosurg. **1**: 23-39, 1944.

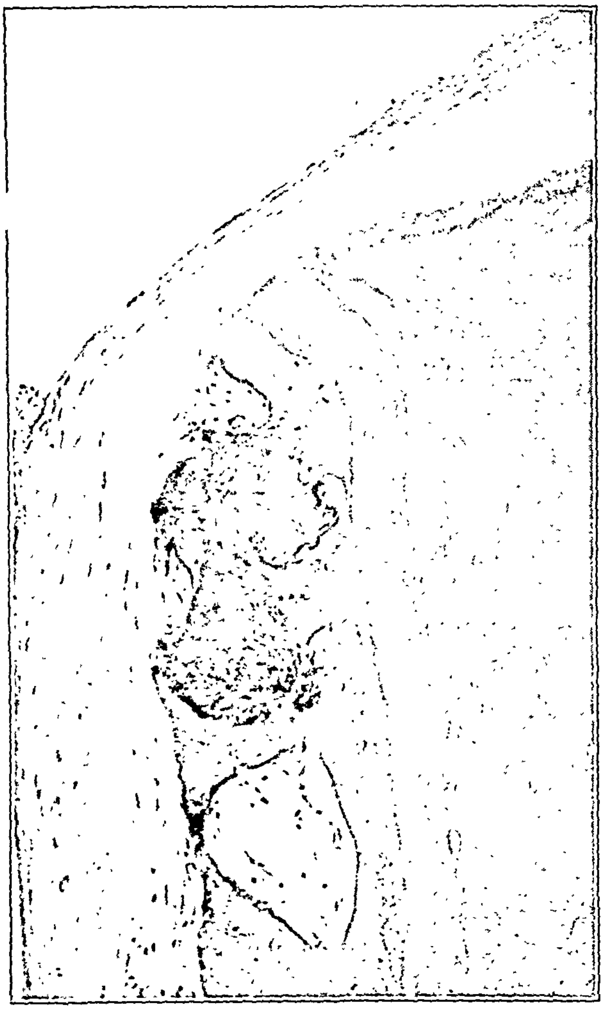

Fig. 6 (monkey 53).—Photomicrograph of the thin fibrous tissue membrane which formed between the cut surface of bone and polyethylene tube placed in a saw cut in the cranium one hundred and ninety-seven days previously (hematoxylin and eosin). Note the smooth surface of the membrane and the lack of foreign body reaction or new bone formation.

Ingraham, Bailey and Cobb[14] have showed that fibrin film placed over damaged cortex aids in the prevention of meningocerebral adhesions, and it is not anticipated that polyethylene film will replace fibrin film in this application. However, polyethylene film, possessing great pliability, low specific gravity, relative transparency and the ability to hold silk sutures securely, should be superior to either fibrin film or tantalum foil as a dural substitute when a watertight closure of dural defects is required. Polyethylene film is much less expensive than tantalum foil and should be an adequate substitute for it in its other surgical uses, such as in the practice of wrapping the site of a nerve anastomosis.

III. *Other Experiments*

Brief mention is also made of the experimental application of polyethylene film to bone. The film is well tolerated in saw cuts in the skulls of animals and shows no tendency to incite foreign body response. It is surrounded in bone by a thin fibrous tissue membrane (fig. 6). These experiments will be reported in detail in a separate publication. Polyethylene film and tubing have also been used in contact with major blood vessels; they do not cause the formation of fibrous tissue or constriction of the vascular lumen.

Narat and Cipolla,[15] also Huelsebusch, Foter and Gibby,[16] found that certain forms of plastic and rubber tubing caused an inactivation of penicillin. Experiments were therefore conducted to determine the effect of pure polyethylene tubing on penicillin. Samples of polyethylene tubing and rubber tubing were left in contact with penicillin twenty-four hours. The effectiveness of the penicillin solution against a standard strain of hemolytic streptococcus was then tested. The polyethylene tubing did not inactivate the antibiotic, the results being identical with the controls. A sample of rubber tubing inactivated the penicillin 15 to 25 per cent. Studies were not made with streptomycin, since in the experiments of Huelsebusch, Foter and Gibby none of the plastics, no matter how impure, had any effect on streptomycin.

COMMENT

There is a great variety of plastic materials available to industry, but only a small number of these can be used within the human body. Up to the present time, no plastic material which can be formed into pliable tubing as a substitute for rubber or into thin film to replace normal membranes in the body has been found. The experiments described in this report suggest that polyethylene in the form of tubing or film can be implanted safely into the tissues, providing pure polyethylene is used.

In neurosurgery the use of the tubing for constant drainage of ventricular or subarachnoid fluid immediately suggests itself. It should also be useful in the drainage of ventricular fluid into the subarachnoid space according to the method described by Torkildsen.[17] The film may well fill the need of a substitute for normal dura when for some reason the dura cannot be used to cover the cortex.

This paper is intended as a report on the experimental application of this interesting and potentially useful material to neurosurgical practice. It has already been used to a limited extent in human patients with completely satisfactory results. Further animal experimentation and clinical trial will determine its value in other fields of surgery.

CONCLUSION

1. Animal experimentation with a new synthetic plastic material, polyethylene ("polythene") in the form of flexible tubing and film has shown it to be well tolerated in animal tissues when used in pure form. There is no foreign body reaction, the tissue response being similar to that seen in the use of tantalum and methyl methacrylate.
2. Polyethylene does not inactivate penicillin.

SIGNIFICANT TRENDS IN CANCER RESEARCH

STANLEY P. REIMANN, M.D.
Philadelphia

Medicine is applied biology. Medical problems, therefore, are fundamentally biologic problems. This includes cancer, which was recognized as belonging in this sphere many years ago by a few pathologists but, curiously enough, remained with little attention on the part of biologists themselves until quite recently.

Until comparatively recently, cancer was studied mostly in its gross pathologic-anatomic aspects. Better microscopes made possible enunciation of the cell doctrine, whereupon cancer was placed in its true category of being a cellular growth and maldevelopment. Even so, few biologists, in whose fields the problems of cellular growth and development are paramount, recognized the relationship to a sufficient degree to work on it. Virchow's dictum that all cells come from preexisting cells led to a persistent search for cellular beginnings, and the literature teems with demonstrations which often were anything but conclusive as to the exact cellular origin of the various types of cancer.

A serious difficulty faced by pathologists in this type of work is lack of sufficient knowledge of the growth and development of normal cells for comparison. The pathologist studies a tumor as of the instant when it is removed and fixed and from this point tries to figure out what happened when the tumor arose and how it progressed while it was still in the patient. The hazards need no emphasis. To prophesy the future of a given tumor on the basis of what it looks like at one fleeting instant of its life is to assume wishfully that all the variables but one are controlled. Most pathologists now realize this. In the last analysis, prognosis as to the fate of a patient with cancer depends not on the type of cancer, its cellular details, behavior of the cancer cells or the name given to it but on whether or not, in its treatment, every last cancer cell has been removed or destroyed. Some surgeons and/or radiologists still refuse to be radical in the presence of a small cancer or of one said to be of low malignancy. A good maxim is "faint heart never cured cancer patient." Of what use otherwise is the propaganda "come early"?

The need and value of comparing malignant growth with the corresponding normal has been generally admitted only since the end of the first world war. In fact, it is now emphasized that the use of biologic technics offers a most fruitful approach to cancer. The programs of the Cancer Research Association of not so many years ago will be remembered. Cancer itself was studied and mostly in its pathologic-anatomic aspects. The occasional biologic paper on growth and development of normal cells was believed to be "interesting though not applicable." The programs of recent years, however, present biologic, chemical and physical papers in the majority. This is a significant trend. Biologists in general now recognize the cancer problem as one to which they can contribute, and workers in cancer research welcome them into the fold. Pathologists, now fully appreciating the need, keep a weather eye open for studies of normal cell behavior as well as continuing their own studies of pathologic cells.

THE BIOLOGIC APPROACH

The crucial problems in the biologic approach are the differentiation and organization phases of cellular growth. Cancer cells, while differentiating even to high degrees at times, nevertheless show qualitative anatomic differences from corresponding normal cells. Translate this fact from static to dynamic terms. How does the cancer cell get that way? And translate again from this language to chemical and physical terms. Devise methods of quantitative estimation of degrees of differentiation. How far can a cell normal or cancerous differentiate until it can no longer divide? What potencies remain in cells after some of their original complement has been expressed? What environmental chemical factors govern potencies and with what intracellular substances do they react to form what new substances? What are the qualitative changes when a cancer cell or cells originate? What are the enzyme patterns catalyzing these reactions both in the normal and in that "new" cell that is cancerous; in that cell which has undergone "somatic mutation"; in that cell which is no longer quantitatively different but qualitatively?

A similar set of questions is constructed for the organization problem. Cancer cells do not organize into organs and parts as do normal cells. Here the separated problems of blood supply, nerve supply, organizer substances (Spemann), hormones, function (Wilhelm Roux) enter the picture.

The applications of these problems are not only in such general questions as causation but also in details such as origin, cellular patterns, diagnosis and even nomenclature, which should be changed from the weird and confusing words now used to a more logical and accurate language. For example, instead of saying that a squamous cell carcinoma arises from squamous cells, it should be stated that a squamous cell carcinoma arises from but partially differentiated cells and they differentiate out into squamous-like cells.

Another part of the biologic approach which has helped stimulate biologists but also has medical interest is the recognition that cancer is not confined to human beings but has been found in most multicellular organisms. In addition to the spontaneous tumors studied in horses, dogs, fish, turtles, frogs and mice, botanists have shown that much can be learned from plant tumors. As one clinician said, "At least I can tell patients and their relatives that the fundamental cause of their cancer is not too much worry, or eating food cooked in certain pots, or sleeping with their beds east and west, because fish do not eat tinned food, nor do geraniums worry, and yet they too get cancer."

VIRUSES, GENES, NUCLEOPROTEINS

The discovery by Bittner of the transmissible agent in mammary cancer has forced acceptance of the belief that much more intensive study of viruses and cancer must be done. Clearer chemical characterization of the

---

From the Lankenau Hospital Research Institute and the Institute for Cancer Research, Inc., Philadelphia 30.

Read in the General Scientific Meetings at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 9, 1947.

transmissible milk agent is being made, and coordination with other virus studies and nucleoproteins brings wide fields into focus. X-rays cause mutations in such organisms as Neurospora, yeasts, paramecia which are correlated with their genes, their nucleoproteins, their nutritional requirements and their intermediary metabolism, all points of departure in cancer research.

NUTRITION AND CANCER

Reduction in caloric intake of about one third reduces the expected incidence of breast cancer in inbred susceptible strains of mice but apparently by indirection, for their ovaries, uteri and breasts were atrophic, suggesting pituitary insufficiency. Reduction in caloric intake reduces also the development of leukemia in methyl cholanthrene-painted mice but not if the calories are largely supplied by fat. Other hints are in the literature concerning fats and carcinogenesis but details await further experiment. Protein restriction also nhibits tumor formation but again by indirection. In ief, nothing specific has been found except for a few bstances like dimethyl-amino-azobenzene, which produces cancer of the liver but which are not normal constituents of the diet.

On the other hand, clinical advantage should be taken of the results of general research in nutrition. Patients are better prepared for surgery and/or irradiation by proper attention to diet, and the advanced cancer patient can be made more comfortable.

CARCINOGENS

The story of the carcinogens is a familiar one. Some four hundred compounds are known to produce cancer. There is no general chemical pattern among them. Crucial questions are (1) to find a naturally occurring carcinogen and (2) to characterize the changes in cellular potencies mentioned which are induced by any one of the carcinogens.

Obviously, it is not true to continue saying that we do not know the "cause" of cancer. We know many causes. It depends on what level of language we wish to discuss it.

ISOTOPES

The making available of radioactive and stable isotopes has opened new paths for tracking down the differences between the chemical reactions in cancer and normal tissues by way of their intermediary metabolisms. But to claim that radioactive atoms will eventuate into a "cure" for cancer is somewhat premature. On the other hand, it should not be denied that since such physical agents may produce mutations from the normal to cancer they may do the same for the cancer cell and render it less or perhaps more malignant.

CHEMOTHERAPY

The ideal approach to cancer therapy is to devise measures which will prevent the body from developing an abnormal growth. The next is to devise treatment which will enable the body itself to do away with its malignant growth. Neither surgery nor x-rays and radium fulfil these requirements. Over the years, many substances have been tried, but haphazardly and sporadically. Strangely enough, practically no systematic trials of series of compounds have been made such as resulted in 606 and 914 or as industry tried some 30,000 compounds before a suitable antiknock agent was found for automobiles. Recently, however, groups have been organized along this line. Among compounds tested are the bacterial polysaccharides, colchicine derivatives, nitrogen mustards. Obviously if nothing is tried, nothing will be found. But only those should be used which are justified by experimental results in lower animals. Needless to say, every safeguard must be thrown around patients who are willing for such trials to be made, and they and their relatives must be told of the experimental nature of the procedure. Appraisal of results must be impersonal and objective and only after sufficent time has elapsed.

METHOD OF THINKING—PHILOSOPHY

The foregoing subdivisions by no means exhaust the list; genetics, endocrinology, embryology, statistics and many other subjects contribute to cancer research. Obviously it is necessary to construct an overall picture, not forgetting the clinical aspects. This means there are needed a set of ideas and thoughts; a series of hypotheses; a mode of thinking, so that facts as they come from the various disciplines may be fitted into a rounded whole. This mental exercise is called philosophy, though I fear to use that word. It might hurt the sensibilities of certain scientists who still are not aware of the reconciliation which has occurred during the last half century between science and philosophy. A significant trend in this direction is the fact that within the last six months I was actually asked to speak on the philosophy of cancer.

Is there any doubt that the various facts in cancer should be coordinated, correlated and developed into a whole? Is there any doubt that an integrated program of research should be constructed and definite questions for answer be posed by both clinical and laboratory experiments?

RESEARCH ORGANIZATION

As cancer is fundamentally a biologic problem, a proper research staff must consist of specialists in all subdivisions of biology, among them embryology, genetics, anatomy, biochemistry, biophysics, protozoology, cytology, botany, plus a complete clinical staff. Each group develops its problems and mode of attack within the framework of the overall program adopted. Seminars and conferences keep each informed of the others' results; ideas flow, suggestions emerge, the general program and its separate details are critically examined, altered on justification and thus many angles of the larger problems are attacked.

When the Lankenau Hospital Research Institute was organized in 1925 with a group of specialists to investigate growth and development as fundamental to cancer, the idea received little recognition. Twenty-two years later we break ground for a new building, having outgrown our old quarters and having organized a group called the Institute for Cancer Research. There are a number of other groups now with the same point of view and thus with similar organizations.

SUMMARY

The most significant trends in cancer research are:

1. The recognition that cancer is primarily a biologic problem.

2. The organization of groups (too few as yet for the magnitude of the problem) but at least a few composed of specialists in the most diverse lines of inquiry.

3. The recognition of the need of definite overall programs of research.

Lankenau Hospital.

Clinical Notes, Suggestions and New Instruments

A CLINICAL TEST FOR MIGRAINE

MAX T. SCHNITKER, M.D.
and
MAURICE A. SCHNITKER, M.D.
Toledo, Ohio

A Query and Minor Note in The Journal, Oct. 26, 1946, page 486, stated that "there is no satisfactory method of experimentally inducing attacks of migraine in persons who are susceptible to them." Since 1940 we have been using a test which we find quite specific in precipitating a migraine headache in persons afflicted with them. This test consists in the use of nitroglycerin sublingually.

Migraine is a distinct type of headache and should be separated from so-called histamine cephalalgia, which can be precipitated by the subcutaneous injection of histamine base according to the method of Horton[1] It has been fairly well established by Wolff[2] and his co workers that the basic mechanism of pain in the migraine syndrome is due to the stretching of the cranial arteries, chiefly the extracranial structures (external carotid artery and its branches). This same mechanism obtains in the headache associated with arterial hypertension. Conversely, the headache of histamine cephalalgia, and that associated with fever, is due chiefly to dilatation of the cerebral branches of the internal carotid, the vertebral and the basilar arteries.

In 1938 one of us (M. T. S.) working with Northfield[3] demonstrated that the principal action of histamine in producing headache is on the internal carotid artery and its branches. Similarly, we are accumulating evidence to suggest that the principal effect of nitroglycerin in producing a headache is on the external carotid artery and its branches.

The following may be used as an office procedure in the examination of a patient for headache

With a history typical of, or strongly suggestive of, migraine headache, the patient is made to rest quietly on the examining table, with a sphygmomanometer cuff in place. It is important that a careful neurologic examination has been made to rule out intracranial pathologic conditions. A headache should not be present when the test is begun; if there is slight headache, the test can still have significance. On the other hand, if a typical headache is present the test usually will not give any added information. Finally, to obviate any psychologic effect, the patient is not told that one is going to attempt to reproduce a headache.

After the blood pressure and resting pulse have been recorded, the patient is given two tablets of 1/100 grain (0.6 mg.) size of nitroglycerin (the hypodermic soluble tablet preferred), which constitutes 1/50 grain (1.3 mg.), under the tongue. (Amyl nitrite does not work as well in reproducing the headache in persons subject to migraine.) In the first two minutes there will be little or no change in the pulse, but the blood pressure may rise slightly in some patients. Between the second and fourth minutes the pulse will rise, the blood pressure will usually drop to below the resting level and the patient will begin to complain of symptoms. Without suggestion, or too direct questioning, the conversation of the next few minutes will usually reveal whether the symptom produced is the same as the headache which constitutes the patient's complaint. The patient may then be asked to compare the sensation produced by the tablets with the headache of his complaint. On rare occasions a patient may develop syncope with this procedure, indicating that the dose was too large. One 1/100 grain (0.6 mg.) tablet is then often sufficient to use in a subsequent test. In the vast majority of cases, however, 1/50 grain (1.3 mg.) appears to be optimum and does not produce any untoward effect.

When a patient's symptom has been localized to one area of the head, as frontal, temporal or occipital, that area will usually be the first to manifest typical pain with the nitroglycerin test. A more generalized headache may follow a few minutes later in some persons.

After the patient has thus been given a headache, it is only right that it be relieved; this can usually be done easily by firm compression of the carotid artery on the involved side for one or two minutes. If that does not give prompt relief the patient may be given 100 per cent oxygen to breathe for five minutes or a solution of 0.5 to 1 mg. ergotamine tartrate intravenously. On the other hand, if the patient is left to rest quietly, with no attempt made to relieve the headache, it will usually disappear spontaneously in ten or fifteen minutes.

Often the production of the headache with the nitroglycerin and its prompt relief by carotid compression are so striking that at this point an obvious psychologic effect comes into play. For the patient now feels that the physician understands the mechanism of the headache.

If the test has reproduced the patient's typical headache, the procedure is stopped at this point. In the event that the nitroglycerin has not reproduced the typical symptoms, the patient is allowed to rest for fifteen minutes and is then given the subcutaneous histamine test according to the method of Horton. If this reproduces the patient's symptom, the diagnosis of histamine cephalalgia is made. He is then given 2 or 3 minims of a 1 : 300,000 solution of epinephrine intravenously to terminate the attack, and a program of histamine desensitization is outlined. Thus, the entire procedure can be carried out in no longer than thirty minutes if both tests are done, in ten to fifteen minutes if the nitroglycerin test alone is used.

In correlating the results of the nitroglycerin test with (1) a typical history of migraine and (2) the results of treatment for migraine, we have found the test uniformly satisfactory in over 250 cases. To put it in another way, in those cases in which the nitroglycerin test has reproduced the headache, good results have been obtained by treating the patient for migraine. This has consisted chiefly in the administration of 10 grains (0.65 Gm.) of calcium lactate twice a day, the use of a sedative, such as 1/2 grain (0.03 Gm.) of phenobarbital twice a day, the elimination of allergenic substances when they can be discovered (particularly coffee, chocolate, beans, peanuts and coca-cola) and the use of ergotamine tartrate, 2 to 4 mg. under the tongue, at the onset of an acute attack.

Since pain is entirely a subjective phenomenon, the success of the test lies solely in the ability of the person to identify the headache produced by the nitroglycerin in comparison with his former complaint. This is astonishingly accurate in most patients, particularly in the more intelligent group in which migraine is most prevalent. The nitroglycerin test will not reproduce the headache of a nervous tension state with its dull or binding type of pain due to spasm of the occipitofrontalis muscle. Nor will the nitroglycerin test reproduce the headache of the post-traumatic cerebral contusion syndrome, which is a dull ache with intermittent, sharp, shooting pains situated deeply and usually associated with dizziness. However, the sharp, throbbing pains of the scalp (traumatic migraine) that are localized to the site of an injury along the course of one of the extracranial arteries are usually reproduced accurately by the administration of nitroglycerin, as would be expected. Since most atypical facial neuralgias are of vascular origin, due to distention of the external carotid branches, they are similarly reproduced by the nitroglycerin test. In contrast, true trigeminal neuralgia (tic douloureux) is not precipitated by this procedure.

In summary, we have found that the sublingual administration of nitroglycerin, 1/50 grain (1.3 mg.), in the form of soluble tablets is a highly satisfactory method for the experimental production of migraine headache in persons who are susceptible.

EPINEPHRINE IN CARDIAC RESUSCITATION

HENRY K. BEECHER, M.D.
and
ROBERT R. LINTON, M.D.
Boston

In the use of epinephrine in cardiac resuscitation evidence is at hand to show that the effective stimulus is not always the needle prick of the heart wall, as has often been asserted but that the epinephrine itself is important. It may be well to mention also the frequency with which dangerous doses of this agent are used.

The technics of cardiac resuscitation continue to offer much material for debate. Arguments for or against the importance of a given practice have not yet been settled by direct observation in man in many instances. In cases in which it is possible to make direct observations it is important to report the evidence.

REPORT OF CASE

The following case illustrates that the needle prick and massage were not adequate to revive a heart that had failed. The injection of epinephrine and massage of the heart proved adequate on two occasions.

A girl aged 4½ years entered the Massachusetts General Hospital with a diagnosis of the tetralogy of Fallot (ventricular septal defect, pulmonary stenosis or atresia, dextraposition of aorta and hypertrophy of the right ventricle). Physical examination revealed that she was poorly nourished and cyanotic, with clubbing of fingers and toes. The veins of the scleras, forehead and distal parts of the extremities were dilated and tortuous. Polycythemia was present (hematocrit reading 69 per cent, arterial oxygen saturation 62 per cent). The heart was enlarged, and a roentgenogram showed the narrow base typical of the tetralogy of Fallot. The electrocardiogram showed axis deviation to the right. No murmurs were heard, and some doubt as to the correctness of the admission diagnosis was expressed. It was decided, however, that the patient deserved surgical exploration.

After the administration of 0.32 mg. atropine as a preanesthetic medicament, nitrous oxide with 20 per cent oxygen was used as a preliminary to ether-oxygen anesthesia with closed respiratory system, which included a "to and fro" carbon dioxide filter. The sequence of events was as follows:

At 8:35 the induction of anesthesia started. At 8:45 the trachea was intubated under direct vision through the mouth. The blood pressure was 90 systolic and 65 diastolic; pulse rate was 168. At 9:20 surgical intervention began. The blood pressure was 90 systolic and 60 diastolic. The pulse rate was 190. At 9:38 the pleura was opened. The anesthetist commented that the patient did not seem to tolerate the open chest well. The surgeon was notified.

At 9:55 the heart suddenly stopped; respiration continued. The heart was massaged. The right auricle was repeatedly stuck with a needle; no spontaneous effect resulted from this type of stimulation.

At 10:25, after thirty minutes of cardiac failure, while life was sustained by cardiac massage, 0.2 cc. of 1:1,000 epinephrine hydrochloride solution diluted in isotonic solution of sodium chloride to 2 cc. (1:10,000 concentration) was injected into the right auricle while massage was continued. The heart immediately showed imperfect beats, and in five minutes it appeared to be beating normally. At 10:30 the operation was resumed. At 10:58 cardiac standstill recurred. Massage of the heart again was carried out without any restoration of spontaneous activity, and the heart wall was stimulated by needle pricks for a twelve minute period. No spontaneous effect resulted from this. At 11:10 epinephrine hydrochloride (same dosage as previously used) was injected into the right auricle with immediate effect on the heart. In a few minutes this led to the reestablishment of an apparently normal rhythm. The right pulmonary artery was exposed and found to be exceedingly small, about 3 mm. in diameter. The right innominate artery was exposed and seen to be decidedly short, about 1 cm. in length. The subclavian artery was freed, and it was planned to use this in the anastomosis. At 11:50 because of the patient's general condition it was decided to carry out the operation in two stages. At the end of the operation the patient's blood pressure was 100 systolic and 60 diastolic; the pulse rate was 160.

Subsequent to the operative procedure the blood pressure fell slowly; the pulse became thready and the respirations gasping. The patient died four hours after operation. Autopsy confirmed the diagnosis of tetralogy of Fallot with pulmonary stenosis, ventricular septal defect, patent foramen ovale, dextraposition of aorta and hypertrophy of the right ventricle.

COMMENT

Twice, after periods of cardiac standstill of thirty and twelve minutes, respectively, epinephrine produced resuscitation of the heart although needle pricks had failed to do so. It is often stated with assurance that the benefit to be derived from cardiac injections is to be explained by the stimulation resulting from the needle prick. In this case the epinephrine appeared to be the effective agent on two occasions after repeated needle pricks had failed.

When epinephrine is employed in cardiac resuscitation, doses that seem to us to be dangerously large (namely, 1 cc. of 1:1,000 solution of epinephrine hydrochloride) are often used, with the hazard of production of ventricular fibrillation. The dose used here was possibly larger than that desirable in a child. In adults who have impaired hearts, and any heart in standstill is at least acutely impaired, it is doubtful if more than 0.2 to 0.3 cc. of 1:1,000 solution of epinephrine hydrochloride ought to be used, and this should be diluted ten times before injection into the right auricle. (This may be introduced by way of the right jugular vein.) Accompanying massage of the heart is probably of great importance. Of course oxygenation should be maintained by artificial respiration with an oxygen-rich atmosphere, and the falling blood pressure should be supported by transfusion.

More case reports of this nature are desirable to add to our accumulated experience concerning this important problem.

ADDENDUM

Since this report was submitted for publication a second case has come to our attention: In the course of a pneumonectomy on a man aged 45 the main bronchus was opened. Shortly after the period of accompanying anoxia the heart failed. Artificial respiration and massage of the heart kept the patient alive. During the subsequent fifty-three minutes the heart was pricked with a needle, procaine was used, and the heart stimulated electrically. Of these, only the latter agency produced a transient series of a few imperfect beats. However, fifty-three minutes after the heart had stopped the dose of epinephrine referred to was injected into the right auricle, with prompt resumption of fairly regular but very weak action. For a brief period the radial pulse became palpable. Twenty minutes later another dose of epinephrine was injected into the heart, with some strengthening of the heart's action. Over the next half hour the heart failed completely and the patient died. All one can say in this case is that the epinephrine appeared to be more effective than the other means used to revive the heart. Whether earlier use would have been more effective one cannot say. Possibly it would.

From the Department of Anesthesia and the West Surgical Service of the Massachusetts General Hospital.

POISONING DUE TO TINCTURE OF RHUS TOXICODENDRON

HARRY LOWENBURG Jr., M.D.
Philadelphia

In 1866 Dr. J. W. Moorman of Hardinsburg, Ky.,[1] reported the cases of 2 children who each ate about 1 pint (550 cc.) of the fruit of Rhus toxicodendron, or poison ivy. In a few hours they became drowsy and stuporous, and in a short time vomiting commenced. The vomitus at first consisted of the partially digested fruit, and this was followed by a thick tenacious fluid the color of red wine Generalized convulsions then appeared accompanied by delirium The respiratory rate was hurried, the pulse weak and rapid and the pupils dilated. Emesis was induced, and a solution of sodium carbonate was freely administered. Both children recovered. In 1867 there was reported[2] the case of a boy who drank tea made from the root of R. toxicodendron. He became delirious, and there developed nervous twitchings, watery eyes, an intense burning sensation in his stomach and an intolerable cutaneous itching which was accompanied by a measleslike rash and high fever. He recovered. In 1852 a medical student took 1 gill (118 cc.) of a strong concoction of the leaves and vines of R. toxicodendron after supper.[3] The following morning his face was swollen; he slept nearly thirty-six hours In 1921[4] Alderson reported fatal results among Indians and Mexicans from eating the leaves of the poison oak plant, Rhus diversiloba.

Since the introduction in recent years of the use of extracts of R. toxicodendron for oral immunization against poisoning due to ivy and sumac there have been many reports of local and systemic reactions.[5] These are (1) local irritations of the skin and mucous membrane which come in direct contact with the extract and (2) generalized pruritus with or without a rash, especially about the anal region. There have been no reports in the modern literature of toxic reactions approximating those in the cases previously cited.

A major toxic reaction and near tragedy are the subject of this report. These occurred in a patient who presented a most perplexing problem in differential diagnosis.

REPORT OF CASE

History.—J. S., a white boy aged 11, was admitted to the Jewish Hospital at 12:30 a. m. on May 5, 1946 with a chief complaint of headache, nausea and vomiting of twenty-four hours' duration.

Past Medical History.—In 1942 the patient was seen because of a complaint of enuresis. It was noted at that time that he was small for his age and that his speech was slightly slurred. Further investigation revealed a bilateral congenital stricture of the ureterovesical junction. This was associated with a slight hypertension (blood pressure 120 systolic and 80 diastolic) and an elevated blood urea nitrogen (32 mg. per hundred cubic centimeters). Enlargement of the ureteral orifices with the electric knife (Dr. John B. Lownes) was followed by an immediate return of the blood pressure and blood urea nitrogen to normal limits. Within the next six months he grew 2½ inches (6.4 cm.) and his speech cleared. Culture of the urine revealed a nonhemolytic streptococcus, which promptly recurred after chemotherapy. The bacilluria persisted over the years, but there were no local or systemic reactions at any time. The enuresis disappeared. On two occasions the vesicoureteral junctions were dilated under general anesthesia (Dr. Meredith Campbell). The first dilatation on Oct. 8, 1945 was followed on the next day by urticaria that was confined to the region of the face where the anesthestic mask had been secured in place and to the penis where manipulations had occurred. This urticaria was obviously of traumatic origin in a hypersensitive person. The last dilatation was done on April 25, 1946, ten days prior to the onset of the present illness. At that time culture of the urine revealed Bacillus pyocyaneus. At frequent intervals throughout his life there developed on the patient's extremities severe rashes which resembled those of dermatitis venenata due to poison ivy. He complained of itching about the buttocks two weeks before the onset of the present illness, but no cause for it could be determined at that time. Unknown to me until thirty-six hours after his admission to the hospital was the fact that the patient had been taking increasing doses of tincture of R. toxicodendron by mouth at irregular intervals for a period of seven weeks.

History of Present Illness.—At 4 p. m. on May 4, 1946 the patient complained of chills and had a rectal temperature of 105 F. Physical examination at that time revealed questionable impairment to percussion and suppression of breath sounds over the left side of the chest. The patient did not appear seriously ill, and 5 grains (0.32 Gm.) of aspirin (acetylsalicylic acid) was given. Shortly thereafter the temperature fell to 101 F., and the decline was accompanied by profuse perspiration. At 8 p. m. the temperature again rose to 105 F., and physical examination revealed no change. Sulfonamide compounds were ordered in full dosage, and additional acetylsalicylic acid was administered. The temperature promptly subsided, but at 11:30 p. m. the patient vomited a wine-colored material and experienced another chill, with a rise in temperature to 106 F. He was sent to the hospital in an ambulance and had a rectal temperature of 101 F. on admission one hour later.

Course in Hospital.—Physical examination on admission revealed a white boy of about the stated age who was in no acute distress. He was intelligent for his age and extremely cooperative. There were no rashes, but a slight bluish mottling was noticeable over the entire cutaneous area. There was no evidence of twitching or other outward manifestations of a neurologic disturbance. Examination of the eyes, ears, nose and throat revealed essentially normal conditions. There was questionable impairment of the left side of the chest to percussion and suppression of the breath sounds in that area. The heart was normal except for the rate, which was 110 at the apex. The abdomen presented no masses or enlarged organs. The genitalia were normal, as were the extremities. There were no glandular symptoms. Neurologic examination was completely normal. A working diagnosis of pneumonitis involving the left side of the chest was made.

Because of the capricious fever and the suggestion of an imminent state of shock a continuous venoclysis of 5 per cent dextrose in isotonic solution of sodium chloride was immediately begun. Penicillin, 30,000 units, was given subcutaneously.

At 2 a. m. the patient was resting comfortably. The temperature was 103 F., but the pulse rate was 160. At 2:30 a. m. there suddenly developed a chill, which was shortly followed by a generalized clonic convulsion. At 3 a. m. the temperature was 107 F. The convulsive seizures were continuous and were accompanied by severe vomiting. The vomitus was wine colored. At 3:30 a. m. the temperature was 109.2 F., the pulse rate 160 and the respiratory rate 64.

Ice packs were immediately applied. Continuous oxygen with the B. L. B. face mask was administered. Other emergency measures included gastric lavage with sodium bicarbonate, the administration of adrenal cortex, 5 cc. intramuscularly; phenobarbital, 3 grains (0.19 Gm.) intravenously; paraldehyde, 10 cc. intramuscularly, calcium gluconate 10 per cent, 10 cc. intravenously, and caffeine sodium benzoate, 7½ grains (0.48 Gm.) subcutaneously. The continuous venoclysis was discontinued with the onset of the first chill because of the possibility of pyrogens, but the extreme shock made it imperative to immediately start another.

At 4 a. m. the temperature was 105.4 F., the pul [illegible] and irregular to count. The blood pressure [illegible] unobtainable. At 5 a. m. the [illegible] peratur[illegible] was 104 [illegible] rate 170 and the respiratory [illegible]. At [illegible] m. [illegible] was 104.8 F., the pulse rat [illegible] d th [illegible]

Following the administration of paraldehyde the convulsions ceased (about 5 a. m.) and the extremities were spastic. Respirations remained labored, and the oxygen and face mask was discontinued, as it was considered that the patient was rebreathing an excessive amount of carbon dioxide and there was no severe cyanosis. This was rewarded with an improvement in the respiratory rate. During this period musical rales were heard throughout the chest and the breath sounds were suggestive of an asthmatic type of breathing.

Because of the history of infection of the urinary tract and retrograde pyelography ten days before admission, it was thought that the entire clinical state of the patient could be caused by an acute form of pyelonephritis with septicemia. For this the patient was given massive doses of penicillin by all parenteral routes and 40 grains (2.59 Gm.) of sulfadiazine sodium intramuscularly. With the knowledge that B. pyocyaneus had been present in the urine, streptomycin was obtained and 100,000 units was given every three hours. The administration of adrenal cortex was repeated every few hours because of the possibility of a Waterhouse-Friderichsen syndrome and the vasomotor collapse.

The patient's condition remained extremely critical for the next forty-eight hours. At 10:15 a. m. on May 5, 1946 his respirations ceased. Artificial respirations were immediately begun, and 1.5 cc. of nikethamide was given intramuscularly. The respiratory rhythm was restored; it remained irregular for about a half hour and gradually returned to an even rate of about 60 per minute. At 2 p. m. 350 cc. of whole citrated blood was given slowly by the intravenous route. The patient reacted well to this procedure, and an additional 250 cc. was given at 6 p. m. The temperature remained between 103 and 104 F., gradually subsiding to 101 F. at midnight on May 5, 1946. At this time the pulse rate was 140 and the respiratory rate 38. The blood pressure was 110 systolic and 66 diastolic.

For the ensuing forty-eight hours the temperature, pulse rate and respiratory rate slowly returned to normal. The patient was in a deep stupor, but he could be aroused and would attempt to follow simple commands. He was able to swallow water but was incontinent of urine and feces. His general condition improved rapidly and the spasticity of his extremities disappeared, but he retained evidence of damage to the central nervous system, as described in the neurologic report:

Neurologic Examination.—Neurological examination by Dr. Bernard Alpers on May 9, 1946 revealed the following: The boy was alert and responsive. There was two-thirds ptosis of both eyelids. The pupils were slightly dilated and reacted promptly to light over a small arc. The optic nerves were well defined and had good color. The retinal vessels looked healthy. The patient had complete paralysis of upward gaze and of near convergence. He rotated the eyeballs horizontally but the range did not come out to either the inner or outer canthus completely. The corneal reflexes were decreased. There was weakness of the orbicularis palpebrarum and probably some weakness of the muscles of facial expression. The tongue protruded in the midline.

The patient had feeble handgrips but good power of the arms and the right leg. The left leg was weak. The finger-nose test was carried out slowly and fell short of the goal bilaterally. The heel-knee test was not carried out. There was no dyssynergia. The biceps, triceps and radial reflexes were not obtained. The patellar and achilles reflexes were decreased. The abdominal reflexes were absent. There were no pathologic reflexes. Pain position and vibration senses were normal.

The impression was gained that this boy had paralysis of upward gaze, near convergence and decreased power of the left leg. In addition he had decreased corneal reflexes and absent arm reflexes. He had evidence of a lesion in the superior collicular, periaqueductal and hypothalamic region. It was believed that he had a hemorrhagic encephalitis and an encephalopathic condition associated with intoxication due to R. toxicodendron. It was not believed that he had an infectious focus of encephalitis. His condition was considered compatible with recovery.

The patient underwent a transient change in personality, the return of which to normal was accompanied by an amazingly rapid and complete recovery of the use of all his ocular muscles. The weakness of the left leg similarly disappeared. On May 21, 1946 he was discharged, completely cured.

COMMENT

During the first thirty-six hours of the patient's illness the cause of the dramatic course of events was obscure. On the basis of the history of congenital defect of the urinary tract, chronic bacilluria and surgical manipulation ten days prior to the onset of symptoms a diagnosis of acute septicemia seemed justifiable, and treatment was mainly directed toward the cure of this disease. However, the wine-colored vomitus, extreme hyperpyrexia and manifestations of involvement of the central nervous system were not satisfactorily explained. The mystery was deepened when the blood and spinal fluid cultures were reported negative. The parents were carefully questioned, and it was then discovered that the boy had been taking increasing doses of tincture of R. toxicodendron by mouth. After his recovery the patient volunteered the information that he would forget to take the drops for a few days but add the drops for the missing days to the succeeding dose. The last dose, the day before this illness, was 57 drops (about 3.5 cc.). The maximum dose recommended on the manufacturer's label for adults is 5 drops three times daily in half a glass of water. The patient stated that he used only a little water to get it over with quickly. There had been an interval of ten days without drops, and the dose was stepped up by the patient from 45 to 55, 56 and 57 drops on successive days just prior to his admission.

Several dermatologists familiar with the use of this drug and the manufacturers were consulted, and they were not familiar with any patients with a similar response. However, all other possible etiologic factors were eliminated, and knowing this boy's extreme hypersensitivity I cannot help but be convinced that the drug was the sole cause of this remarkable episode. In retrospect it must be admitted that the pruritus of which the patient began to complain two weeks prior to the onset was in fact a mild toxic reaction to the drug. The patient then desisted from taking the drops for about ten days, following which he resumed the medicament at a comparably higher dosage. For thirty-six hours prior to the onset of fever the patient complained of nausea, which undoubtedly was due to gastritis. This became hemorrhagic, which explains the wine-colored vomitus. The subsequent neurologic evidence of damage in the periaqueductal region denotes either a direct effect of the toxin in this area, which involved the temperature control center, or an allergic outpouring, which produced the same result as that described by Kennedy. The complete recovery of the patient is a point in favor of the latter mechanism. The asthmatic type of breathing and the evidence of pulmonary edema are also consistent with an acute allergic reaction.

Urushiol is the active chemical factor common to ivy, sumac and lacquer trees. Stevens[5a] has stated that standardization of extracts can only be approximated because urushiol has not been obtained as a uniform product by the various methods of extraction. In addition Goldman[6] has stated that the definition of the correct dose in the use of tincture of R. toxicodendron is difficult because of varying sensitivity among different persons. He obtained cutaneous reactions or pruritus in 16 of 18 children who took an initial dose of 3 drops of the tincture a day.

Note.—Since his recovery the patient has experienced two severe attacks of dermatitis venenata due to poison ivy.

SUMMARY

1. A case of poisoning from an overdose of tincture of Rhus toxicodendron is reported in a boy aged 11. There developed a temperature of 109.2 F., gastritis and damage to the central nervous system. Recovery was eventually complete.

2. Extreme caution should be exercised in the administration of tincture of Rhus toxicodendron by mouth.

PARALYSIS OF THE BLADDER IN POLIOMYELITIS

ROBERT B. LAWSON, M.D.
and
FRED K. GARVEY, M.D.
Winston-Salem, N. C.

Since we are now entering a new season of increased incidence of poliomyelitis, this preliminary report is being made regarding the use of furfuryl trimethylammonium iodide ("furmethide") for one of the complications of this disease, paralysis of the bladder. The bladder is involved in 10 to 20 per cent of all patients with poliomyelitis, with more involvement in adults than in children. Usually this is manifested by distention and inability to void, but overflow dribbling may occur, and occasionally there may be hyperirritability of the vesical neck with frequency and dysuria. This disability may be overcome in some patients with the aid of hot applications to the area of the bladder and other nonspecific measures. However, many patients need to be catheterized one or more times before spontaneous voiding reappears, although eventually all do recover.

During the 1944 poliomyelitis epidemic in North Carolina we were again impressed with the desirability of trying to avoid catheterization in patients with poliomyelitis. An attempt to cause emptying of the bladder by the use of parasympathetic stimulation was therefore tried. Neostigmine methylsulfate, physostigmine salicylate and acetyl-beta-methylcholine chloride ("mecholyl chloride") may be used for this purpose, but usually the effect of these drugs on the bladder is not apparent before other troublesome side effects become evident. For this reason we chose furfuryltrimethylammoniumiodide[1] a new parasympatheticomimetic drug with particular action on the bladder.[2]

The results with this drug are illustrated in the following 2 case reports of 2 of the patients treated in this series.[3]

REPORT OF CASES

Case 1.—J. M., a boy aged 5½ years, was admitted to the Hickory (North Carolina) Emergency Polio Hospital on June 26, 1944 with typical signs of poliomyelitis. The onset of the illness was five days before admission, characterized by fever and sore throat. Lumbar puncture three days before admission revealed 110 white cells, the type not known. On the day of admission paralysis of the legs and difficulty in voiding were noticed. On admission there was found decided stiffness of the neck and back, moderate weakness of the right leg and pronounced weakness of the left leg. Shortly after admission treatment of the muscular spasm with hot packs was started. The child voided three times during the first day, but the bladder never emptied.

When first seen by one of us on the next day (six days after onset) he had not voided for nine hours, and the bladder reached the umbilicus. Attempts to make him void by hot applications and suprapubic pressure were unsuccessful. At this time 2 mg. (0.4 cc.) of furfuryl trimethylammonium iodide were given subcutaneously. In three minutes the bladder was noted to be contracting, and immediately thereafter the child voided approximately 420 cc. of urine. Four hours later he was given 5 mg. of the drug by mouth and voided again. There was no further difficulty with voiding.

Case 2.—S. M., a boy aged 22 months, who weighed 25 pounds (11.3 Kg.) was admitted to the pediatric service of the North Carolina Baptist Hospital on March 1, 1947. The onset of his illness began four days before admission and was characterized by fever, irritability and general malaise. The day before admission he was noticed to be limping. On admission he was moderately ill, his neck and back were stiff and his right leg was weak.

Lumbar puncture revealed a slight increase of pressure, a negative Pandy test, 1 polymorphonuclear leukocyte and 29 mononuclear leukocytes. He had voided freely before admission and once after admission, but on the second day he had been unable to void for thirteen hours, and his bladder became distended to the umbilicus. At this time he was given 1.5 mg. (0.3 cc.) of furfuryl trimethylammonium iodide subcutaneously without the occurrence of voiding or other parasympathetic manifestations. Two hours later he was given 2.5 mg. (0.5 cc.) of the drug subcutaneously. Within five minutes he voided 345 cc. Four hours later, his bladder was again distended and he could not void. Approximately five minutes after he received 2.5 mg. (0.5 cc.) of the compound subcutaneously he again voided approximately 300 cc. The following day he voided spontaneously. He had no further trouble voiding.

Subcutaneous Dosage of Furmethide

Age of Patient	Dose
0 to 4 yrs.	1.25 to 2.5 mg.
5 to 9 yrs.	2.00 to 3.0 mg.
10 to 14 yrs.	2.50 to 5.0 mg.
15 to 19 yrs.	2.50 to 5.0 mg.
Over 20 yrs.	5.00 to 7.0 mg.

COMMENT

Twenty-five patients with paralysis of the bladder from poliomyelitis have been treated with furfuryl trimethylammonium iodide subcutaneously with complete voiding in less than fifteen minutes in over 70 per cent of the cases. Most of the failures occurred early in this study and can be explained on the basis of inadequate dosage or previous repeated catheterizations.

This drug is available in ampules containing 5 mg. per cubic centimeter for subcutaneous use. The tentative dosage schedule we are using is shown in the accompanying table. The smaller dose should be given initially in order to avoid overdosage. If voiding, flushing or sweating do not follow the subcutaneous administration of the smaller dose, the larger dose may be give

[3] We wish to express our appreciation to Dr. ul, Director of the Hickory Emergency Polio Hospital, pera the members of his staff in this study.

in thirty to sixty minutes (as in case 2). Minor unpleasant side effects of this drug are sweating and feelings of chilliness. One or both of these occurred in 5 of our patients, but none of these was alarming. Severe effects which might follow overdoses of the drug are lacrimation, salivation, prostration and dyspnea. These effects can be easily corrected by the subcutaneous administration of atropine.

Furfuryl trimethylammonium iodide is also available in tablet form for oral use, which requires about four times the subcutaneous dose to effect emptying of the bladder, but the drug is not as dependable by this route. Further studies are being made on the oral use of this agent and will be reported in a more comprehensive report at a later date.

SUMMARY

By the use of furfuryl trimethylammonium iodide ("furmethide"), a new parasympathetic stimulating drug, catheterization can be avoided in most patients with paralysis of the bladder from poliomyelitis.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

TISSUE REACTIONS FROM ANTIGENS

The Council has adopted the following report for publication. In expressing appreciation to Dr. Ehrich for his excellent paper, the Council desires to emphasize certain points for consideration, relating to a discussion of adverse effects following the introduction of foreign antigens into the body, namely: local antibody formation; local damage; inflammatory proliferation; amelioration by the lessening of rapid spread; freedom from bias in the determination of optimal dosage; and the danger of hypersusceptibility. Observance of these and other factors is necessary for attainment of the proper use of antigens and for stimulation of constant research toward new ideas and continued advance in therapeutics. Austin Smith, M.D., *Secretary*.

THE SIGNIFICANCE OF THE TISSUE REACTIONS CAUSED BY ANTIGENS

WILLIAM E. EHRICH, M.D.
Philadelphia

With the introduction of polyvalent vaccines into medicine, the question has been raised whether or not it is safe or profitable to prescribe such vaccines. As antigens are not inert, large quantities of bacterial cells may be expected to have damaging effects. Where is the borderline of safety? Also of concern is the question whether the simultaneous introduction of several antigens produces the same degree of protection per antigen as the isolated administration of these antigens at different times. In brief, what is the optimal procedure of administering antigens? As this is an important question, I was glad to fill the request of the Council on Pharmacy and Chemistry to undertake an inquiry into certain experimental evidence involved in this problem, with special consideration of the various mesenchymal reactions that may be caused by antigens.

The introduction of an antigen into a tissue causes, as is generally known, an inflammatory reaction. Depending on the nature of the antigen and the immunologic status of the host, the reaction at the site of injection may be dominated by the presence of granulocytes or macrophages or both; or lymphocytes and plasma cells may be the predominating elements. While these changes take their course, antigenic material is carried through the afferent lymphatic vessels to the regional lymph node, where at first it causes accumulation of granulocytes or macrophages, or both, but soon produces decided proliferation of lymphocytes and possibly also of plasma cells; the lymphocytes are subsequently carried through the efferent lymphatic vessel via the thoracic duct into the general circulation.

The significance of these phenomena now appears to be clear. The granulocytes and macrophages phagocytize and digest formed antigenic material. One to two days after the injection of bacteria large quantities of dissolved antigen can be demonstrated locally in the tissue and in the efferent lymphatic vessel.[1] The reaction in the lymph node, on the other hand, is associated with the production of antibody; this begins to appear here on the third or fourth day and reaches its highest concentration on the sixth or seventh day after injection of the antigen;[2] at the place of injection, antibody titers remain low. These various observations indicate that the proliferation of lymphocytes and possibly also of plasma cells in the regional lymph node are morphologic expressions of good antibody response.

It is common knowledge that an inflammation may lead to hemorrhage, necrosis, suppuration or other undesirable changes locally or in the regional lymph node. Where precisely to draw the line between safety and damage, however, is not certain. There may be considerable overlapping of these two effects. It would be desirable to know which reactions are safe or profitable locally and in the regional lymph node. This may now be determined by injecting various doses of various antigens into the foot pads of rabbits and by comparing antibody production in the popliteal lymph node with the morphologic changes here and in the foot pad.

Though the local phenomena are probably the most important mesenchymal reactions that are encountered in the immunization of human subjects, there may be general reactions of the vascular connective tissue as well. The latter are most prominent after intravenous injections, but they have been observed also after intraperitoneal and subcutaneous injections, particularly of antigens that cause necrosis locally or in the regional lymph node.[3] The appearance of general mesenchymal reactions, if caused by subcutaneous injection, may be regarded as a delicate indicator of insufficiency of the local defense mechanism.[4] As these reactions are little known generally, though an important part of the phenomena under discussion here, they will be presented in detail.

General mesenchymal reactions, i. e., general reactions of the vascular connective tissue due to intravenous introduction of antigens, were first recognized by Oeller and Siegmund in 1922. In his first papers[5]

Professor of Histology, Graduate School of Medicine, University of Pennsylvania; Chief, Division of Pathology, Philadelphia General Hospital.

[5] Oeller, H.: Ueber die Bedeutung der Zellfunktion bei Immunitätsvorgängen, Deutsche med. Wchnschr. **49**: 1287, 1923; Ueber die Bedeutung reaktiv "entzuendlicher Vorgaenge" bei bakterieller Allgemeininfektion, ibid. **357**. 1924; Zur Histopathologie der haematogenen Infektion mit pathogenen und apathogenen Bakterien, ibid., 1924, p. 937.

Oeller described phagocytosis of the injected material by both the reticuloendothelial cells of liver and spleen and the common endothelial cells, particularly of the capillaries of the lungs, with simultaneous transformation of the latter into polymorphonuclear and other leukocytes. These changes were called "endothelial reaction." Later (1925) he[6] described an "adventitial-endothelial reaction" or "general inflammation of the vessel wall" as occurring simultaneously with the endothelial reaction, which was characterized by enormous "lymphoid-plasma cellular transformation" of the vascular connective tissue. There was pronounced cuffing of the blood vessels particularly in lungs, liver and spleen with "very basophilic lymphoid cells with large, clear, round, spindle-shaped or oval nuclei." The lungs also showed "enormous proliferation of the adventitial cells of the capillaries causing thickening of the alveolar septa" and in some animals "enormous proliferation of endothelium, resembling endarteritis and endophlebitis." If the antigen was in solution the first (endothelial) reaction did not develop. While the first reaction reached its peak five to ten minutes after injection, the second reaction did so in thirty to sixty minutes. After twenty-four hours both had disappeared.

As to the nature of the adventitial-endothelial reaction, Oeller believed that the large basophilic lymphoid cells "assumed the shape of lymphocytes." "The lymphoid-plasma cellular reaction showed a specific tendency to differentiate into lymphocytes." As this occurred at the same time as the injected erythrocytes underwent hemolysis, and since the injection of dissolved hemoglobin caused no endothelial reaction but only the production of lymphocytes and plasma cells, he concluded that these cells possibly ingested and metabolized dissolved antigen in a fashion similar to that in which phagocytes handled corpuscular matter.

Siegmund[7] could not confirm Oeller's theory of endothelial reaction but explained it as confusion with phagocytosis of granulocytes by macrophages. However, he also described two different reactions, namely, (1) lymphoid-plasma cellular proliferations resembling Oeller's endothelial-adventitial reaction and (2) changes in the intima of blood vessels which he called "intima granulomas." In highly immunized animals he observed "organoid structures in the adventitial tissue" consisting of hemopoietic parenchyma developing into the direction of lymphatic-plasma cellular as well as myeloid elements." The basophilic cells in the septums of the lungs were interpreted as "hemocytoblasts arising from endothelial and adventitial elements." After injection of proteins Siegmund found a preponderance of lymphocytes; after injection of iron, myeloid-erythroplastic elements.

Siegmund's "intima granulomas" were found in animals that had received massive doses of living colon bacilli (Escherichia coli) intravenously. They were also found in human beings that had died from septicemia. As these were later identified as organized thrombi,[8] they should not be included among the reactions under discussion here.

The lymphoid-plasma cellular reactions of Oeller and Siegmund were soon confirmed, notably by Domagk[9] and Victor Schilling.[10] The latter also observed a decided reaction of the lymphatic apparatus in the spleen and elsewhere with the formation of large secondary nodules with many mitotic figures. However, the rapid transformation of endothelial or adventitial cells into polymorphonuclear leukocytes described by Oeller and Siegmund could not be substantiated; the appearance of granulocytes in the lungs was found to be caused entirely by emigration of these cells from the circulating blood (Schilling).

If in spite of these and other confirmations the general vascular reactions which follow the intravenous introduction of antigen were not generally recognized, this was probably due to the skeptical views of Aschoff and Roesle and their pupils, who held such prominent positions in Germany at that time. It has been pointed out elsewhere[11] that the failure by Seemann, Ewald, Gerlach and others to reproduce these reactions was due to inadequate experimentation (improper dosage of antigen, inadequate time intervals and unsuitable animals). In part, however, it was conditioned by the descriptions of Oeller and Siegmund which were not altogether clear; in fact, a good many of the doses and time intervals given by these authors indicate that in some of their animals the reaction described by them must have existed before the antigen was introduced. Nevertheless, to Oeller and Siegmund goes the credit for having been first to recognize these reactions; they were pioneers in the study of phenomena whose significance is fully realized only now.

The study of the general mesenchymal reactions after the intravenous introduction of antigens received new impetus only in 1929 and 1930, when Ehrich,[12] Epstein[13] and Nye and Parker[14] published their observations. It was shown[12] that the degree and character of the reactions depended much on the dosage of the antigen employed. Repeated intravenous injections of rabbits with 1 to 5 cc. of twenty hour whole broth cultures of Staphylococcus aureus that had been killed by heating for two hours at 60 C. caused only moderate reactions, while injections of the sediment of 40 to 60 cc. of cultures caused enormous reactions, particularly in lungs, liver and spleen. After small doses lymphocytes and plasma cells predominated; after large doses histiocytes and reticuloendothelial elements were the outstanding cells, and there were numerous giant cells of Langhans type. In the rabbits there also developed hyperplasia of the thymus, the lymph nodes and the malpighian bodies of the spleen. The hyperplasia of the thymus was preceded by a drop in weight of this organ even when small doses were given. The latter observation is of considerable interest in view of modern research on the so-called alarm reaction[15] and on globulin production. Research in progress (with Dr. Joseph Seifter) indicates that the weight of the thymus is one of the finest indicators of the alarm reaction, suggesting that even the small doses of Staphylococcus vaccine used in our study were not without toxic effect. As the reactions occurred immediately after the first injection of the antigen, it was concluded that they were not allergic in nature, as claimed by Oeller and Siegmund, but were primary reactions of the mesenchyma to the bacteria or their products. As the animals that received large doses manifested enormous reactions but showed much smaller agglutinin concentrations than those which received small doses and had minor reactions, it was felt that the reactions of the vascular connective tissue denoted damage rather than antibody production.

[14] Nye, R. N., and Parker, F.: Tissue Reactions in Rabbits Following Intravenous Injections of Bacteria, Am. J. Path. **6**: 38, 1930.

In publications with Wohlrab and Voigt[16] it was shown that after the intravenous injection of the centrifugate of 45 to 70 cc. per kilogram of body weight of killed broth culture of Staph. aureus, true plasma cells with eccentric nucleus and a light vacuole in the cytoplasm were comparatively rare in lungs and liver, though more frequent in the pulp of the spleen; the predominating cells were first small and large lymphocytes and possibly monoblasts and later histiocytes and reticuloendothelial cells. Of 28 rabbits receiving these doses once a week for four weeks, 22 showed agglutinin titers under 1 : 1,000, 2 revealed titers between 1 : 1,000 and 1 : 2,000 and 4 showed titers larger than 1 : 2,000. On the other hand, of 10 rabbits which received small doses six times every fortnight for six weeks, 5 showed titers between 1 : 5,000 and 1 : 7,000 and 5 larger than 1 : 10,000. From these facts it was concluded that the reactions observed were not immune reactions but were merely expressions of a pathologic defense reaction (excessive digestion) in contrast to good antibody production as a physiologic defense reaction, the former making its appearance only when the latter failed. In other words, it was considered that the reactions indicated damage, optimal antibody production being induced by doses of antigen that were smaller than those which caused these reactions.

Nye and Parker,[14] who injected rabbits intravenously with 1 to 5 cc. of living or 5 to 10 cc. of killed broth culture of nonhemolytic gamma type streptococci, found also first chiefly lymphocytic and later monocytic reactions especially in the lungs. Rabbits killed after twelve to sixteen injections showed definitely less response than did those killed after five or six injections. As the agglutinin titers remained low (1 : 1,280 and 1 : 2,560 in the two animals tested), skin tests remained negative and injections of nonantigenic materials such as india ink or "collargol" a preparation of colloidal silver and silver oxide stabilized by derived egg albumin, caused essentially the same though less pronounced lesions, it was concluded that they were not reactions of sensitization or immunization, but that they "represented the nonspecific reaction of the rabbit in the process of disposing of certain foreign materials injected into the blood stream."

While Nye and Parker, like us,[16] found no evidence for an immunizing function of the general vascular reactions, Epstein[13] came to a different conclusion. In studying the livers of rabbits given repeated intravenous injections of 0.5 cc. of pig serum, rabbit heart extract, sheep erythrocytes and so forth he observed the appearance in the sinusoids of "medium sized and large, frequently irregularly shaped cells with abundant very basophilic cytoplasm—showing small sickle-shaped or round droplet-like juxtanuclear vacuoles only in occasional cases." Epstein believed that these were derivates of the histiocytes of the liver; his illustrations, however, leave no doubt that these were the same lymphoid-plasma cellular elements described first by Oeller and Siegmund. As the Wassermann reaction, Meinicke reaction and precipitin and hemolysin determinations indicated good antibody response, Epstein concluded that the appearance of the histiocytes was a morphologic expression of antibody production.

It should be noted (1) that Epstein used much smaller doses than my associates and I or Nye and Parker, (2) that he did not find reactions in the lungs of his animals and (3) that his hepatic reactions were lymphoid-plasma cellular rather than monocytic-histiocytic. If we concluded that our reactions were not a morphologic expression of antibody production, we were speaking of the more severe monocytic-histiocytic reactions. Our conclusions, therefore, do not conflict with those of Epstein.

In subsequent years similar observations were reported, notably by Rich, Lewis and Wintrobe[17] and by Smith, Morgan and Mudd.[18] Rich, Lewis and Wintrobe, who studied the behavior of the spleen during immunization, concluded that the large mononuclear cells which proliferated in this organ and presumably were the sources of antibody were not histiocytes but resembled lymphoblasts in all observed respects. Although these cells were not necessarily lymphoblasts in the sense of being immature lymphoid cells, it was conceivable that they were lymphocytes which were greatly enlarged because they performed some special function. On the other hand Smith, Morgan and Mudd, in their study of the histiopathologic changes produced in rabbits inoculated with whole hemolytic streptococci and with certain of their component fractions, came to the conclusion that the parenchymatous degeneration as well as the endovascular and perivascular infiltrations with lymphocytes, plasma cells and histiocytes which developed in their animals were toxic manifestations characteristic of some streptococcic products.

The investigation of the general mesenchymal reactions took a new turn only in 1941 when Bjørneboe introduced quantitative measures into this study. In a first series of experiments[19] several groups of rabbits were injected intravenously with up to eight different types of pneumococci simultaneously, each rabbit receiving 500 million cocci of each type every other day for six months; one group of rabbits received 2.5 billion cocci of one type. It was found that of the animals that received three types of pneumococci all survived the six months of experimentation; of those that received four types the survival rate was 80 per cent, with five types 60 per cent, with six types 40 per cent and with eight types 20 per cent; of the animals that received only one type but five times the individual dose, none survived this period. The antibody response as measured according to Heidelberger and Kabat was enormous. It was observed that with three types of pneumococci antibody production per type occurred with the same rate and in the same quantity as with one antigen; with four or more types, however, there was a decrease in rate and quantity of antibody production per type, though the total volume of antibody was the highest in the animals that received eight types.

[19] Bjørneboe, M.: Serumprotein und Antistoffprotein bei Immunisierung mit mehreren Antigenen, Ztschr. f. Immunitätsforsch. u. exper. Therap. **99**: 245, 1941.

In subsequent experiments Bjørneboe [20] injected first 2 cc. and thereafter 4 cc. of a polyvalent pneumococcus vaccine into the auricular veins of 40 rabbits weighing about 2,000 Gm. each. The vaccine contained 1 billion cocci per cubic centimeter of eight different types. The injections were given every other day for ninety-two days. Nine of these rabbits died during the course of immunization. Another group of 7 rabbits received intravenous injections of a polyvalent Salmonella vaccine containing about 1.4 billion bacteria per cubic centimeter. These rabbits were injected every other day for two months, commencing with 0.02 cc. and then doubling the dose at each injection until it amounted to 2 cc.; this dose was then maintained.

There was excellent antibody production in both series of experiments. In the pneumococcus series, for instance, antibody was found first during the second week of immunization, when the rabbits developed an average of 0.5 Gm. per hundred cubic centimeters of agglutinin globulin as measured by Heidelberger and Kabat's method. During the third week the amount rose to 2.0 Gm., and in the fourth week to 3.35 Gm., per hundred cubic centimeters, but thereafter it decreased again in spite of continued administration of the antigen.

In their studies of the morphologic changes in these animals, Bjørneboe and Gormsen [21] found that the weight of the spleen rose to six times normal (in some animals). The lungs were larger and of firmer consistency than those of the controls. Microscopically there was a moderate plasma cell proliferation in liver, spleen and elsewhere three to five days after the first injection. Most of the plasma cells showed a typical picture with eccentric "wheel nuclei" and a light halo in the cytoplasm. Yet many of the plasma cells, especially in the spleen, had a rather scanty cytoplasm and their nuclei were without the characteristic spoke arrangement; in fact, they corresponded to the cells which Rich, Lewis and Wintrobe [17] had designated as "acute splenic tumor cells." The plasma cellular reaction became more intense, particularly in the spleen, until about the thirteenth day; thereafter it was fairly constant until the thirty-first day, but then it became somewhat less massive. In the animals examined two to three and a half months after the last injection the reactions had completely disappeared.

In contrast to the observations of previous students [22] Bjørneboe and Gormsen at no time saw "any pronounced hyperplasia of the follicles or any distinct proliferation of reaction centers." As good correlation was found between the formation of the antibody on the one hand and the proliferation of plasma cells on the other, it was felt that the latter was the source of the former. It was concluded that either the plasma cells alone produced the antibody or the plasma cells represented functional stages of the antibody-producing cells.

It should be noted that Nye and Parker [14] like my associates and I [23] used considerably larger doses than Bjørneboe and Gormsen, whose doses were between those of Epstein [13] and of Nye and Parker,[14] though closer to the latter. Similarly, the cellular reactions observed by Bjørneboe and Gormsen resembled those of Epstein more closely than those of Nye and Parker or of my group, the cellular response being one of lymphoid cells rather than of macrophages. Our conclusions as to the nature of these reactions therefore conflict with those of Bjørneboe and Gormsen as little as they conflict with those of Epstein.

COMMENT

In summary of the various observations recorded in the literature, it may be regarded as established that the intravenous introduction of bacteria and other antigens, if in sufficient dose, produces general vascular reactions particularly in lungs, spleen and liver. Moderate reactions of this type were observed in rabbits which received repeated injections of 0.5 cc. of pig serum or 1.0 cc. of killed broth culture of Staph. aureus. With larger quantities of antigen the reactions became severer; the most massive reactions were observed with the largest doses of antigen injected (the sediment of up to 70 cc. per kilogram of body weight of killed broth culture of Staph. aureus in rabbits). With moderate doses lymphocytes and plasma cells were the predominating cells; with large doses monocytes and histiocytes prevailed. Because moderate doses that produced lymphocytic-plasma cellular reactions caused excellent antibody production, while with large quantities of antigen the antibody response was depressed, and because much evidence has recently been accumulated to show that antibody production is a function of the lymphocytes and plasma cells rather than of the macrophages, it appears that the appearance of lymphocytes and plasma cells in the intima and adventitia of the vessels during exposure to antigen can be regarded as indicating good antibody production. However, if the vascular response is a predominance of monocytes and histiocytes, it may indicate that the stimulus of the injected antigen has exceeded its optimum.

It is difficult to determine where the borderline between benefit and damage may be. From the experiments of Bjørneboe [19] it would appear that with pneumococci in rabbits this borderline was approached in those animals which every other day received three types of pneumococci, about 500 million of each type; with larger doses, there was less antibody production per type of organism and some animals died during the course of administration. However, the location of this borderline is by no means certain, because I observed an initial drop in the weight of the thymus in rabbits receiving 1 to 5 cc. of killed broth culture of Staph. aureus six times a week every other week.[12] This indicated the presence of an alarm reaction.

A. M. A. MEDAL TO HONOR GENERAL PRACTITIONER

The creation of a midwinter session for the House of Delegates of the American Medical Association and with it a scientific meeting designed particularly for general practitioners was an action of profound significance to physicians and the public. During recent years the need for increased emphasis on the work of the general practitioner has become most apparent. The establishment of the certifying boards in the various specialties has been associated with a tendency to limit the development of general practitioners and also the activities carried on by such physicians in hospitals. To overcome this trend the American Medical Association created a Section on General Practice as a feature of its Annual Session. Now meetings devoted particularly to the needs of the general practitioner at the supplemental session extend still further the interest of the American Medical Association in the education and practice of these physicians.

During the last few years organizations have been established in the field of general practice which have apparently been designed to act as pressure groups to protect the interests of the general practitioner and to forward his work. Since the American Medical Association is the agency which includes the overwhelming majority of physicians in the United States, including a preponderance of general practitioners, the activities of the American Medical Association in this field are likely to have more potency than those of smaller or more localized bodies.

At the meeting of the Board of Trustees in Chicago September 4 and 5 the Board established a special gold medal for a general practitioner who has rendered exceptional service to his community. This award, similar to the American Medical Association's Distinguished Service Medal, which has been given annually since 1938 for scientific advancement in the field of medicine, will be conferred on a general practitioner for the first time at the supplemental session in Cleveland on Jan. 7, 1948. This medal is designed especially to honor a general practitioner who has served as a family physician and who has in that capacity received the recognition of his community. The award will be known as "the medal of the American Medical Association for exceptional service by a general practitioner;" it will include not only the medal but a certificate indicating the reasons for the award. Nominations for this award may be submitted to the headquarters office of the American Medical Association in Chicago by any state medical association or any community service club such as Rotary, Kiwanis or Lions Clubs, by Chambers of Commerce, women's clubs, community councils or similar groups. The nominations should include the name and address of the physician, his scholastic record and a record of his medical service to his community. The nominations may be addressed to the General Practitioner Award, American Medical Association, 535 North Dearborn Street, Chicago 10. When they are received, they will be submitted to the executive committee of the Section on General Practice of Medicine of the American Medical Association, which is composed of Drs. Wingate M. Johnson, Winston-Salem, N. C.; Paul A. Davis, Akron, Ohio, and E. A. Royston, Los Angeles. This committee will select five leading candidates, whose names will be submitted to the Board of Trustees. The Board in turn will nominate three of these to the House of Delegates. On the opening day's meeting at the supplemental session the House of Delegates will receive the nominations together with a record of each of the candidates and will choose by ballot the general practitioner who is to receive the medal.

By this award the American Medical Association will focus the interest of the medical profession and the people of the United States on the tremendous services given to them by general practitioners of medicine. The records of those who are nominated will indicate the range of the activities of such physicians.

THE NITROGEN MUSTARDS (β-CHLOROETHYL AMINES)

At the conclusion of World War I the theory was accepted that mustard gas exerts its vesicant action by releasing hydrochloric acid intracellularly. Studies undertaken at the beginning of World War II have revealed [1] a type of action of the sulfur and nitrogen mustards which is unlike that of any other chemical agent and which resembles in many ways that of x-rays. The principal systemic action of the nitrogen and sulfur mustards is that which causes the death of cells. The cellular susceptibility is related to proliferative activity; thus the formed elements of the blood and the mucosa of the gastrointestinal tract first reflect the cytotoxic action of the mustards. The action of the mustards on the blood forming organs as reflected in the peripheral blood of both experimental animals and man results in lymphopenia, granulocytopenia, thrombocytopenia and moderate anemia. Although diverse systemic effects can be elicited in the mammalian organism by the administration of toxic amounts of the mustards, threshold doses evoke pathologic changes only in cells and tissues which normally exhibit relatively high rates of proliferation and growth. The mitotic activity of a variety of cells from representative unicellular invertebrate, amphibian, mammalian and higher plant organisms is peculiarly sensitive to inhibition by minimally effective doses. Evidence of a direct toxic action on nuclear mechanisms is the appearance of extensive nuclear fragmentation in cells of the corneal epithelium which have been exposed to doses somewhat higher than those which affect only a mitotic inhibition.

---

[1] Gilman, Alfred, and Philips, F. S.: The Biological Actions and Therapeutic Applications of the B-Chloroethyl Amines and Sulfides, Science **103:** 409 (April 5) 1946.

The effects of the mustards on lymphoid tissue, coupled with the finding that actively proliferating cells are selectively vulnerable to the cytotoxic action of the mustards, suggested the therapeutic use of these compounds in the treatment of neoplasms of lymphoid tissue. Of the many substances studied, two variants of special importance have emerged: *tris*(*β*-chloroethyl) amine hydrochloride and methyl-*bis*(*β*-chloroethyl) amine hydrochloride. These two nitrogen mustards are water soluble, crystalline compounds which can be readily dissolved in sterile saline solution for intravenous administration. Experiments on transplanted lymphosarcoma in mice revealed that dissolution of such tumors could be rapidly effected, although the dose required bordered on the toxic, and the tumor invariably returned. The first clinical trial of the nitrogen mustards was conducted by Gilman and his associates on a group of 6 patients in the terminal stages of various neoplastic diseases. The results were sufficiently encouraging to warrant further clinical experimentation.

Goodman and his associates[2] described the action of the halogenated alkyl amines (nitrogen mustards) in the treatment of lymphosarcoma, Hodgkin's disease, leukemia and a limited number of allied and miscellaneous disorders. In all, 67 patients have been studied. Encouraging results have been obtained in Hodgkin's disease, lymphosarcoma and chronic leukemia. In the first two disorders dramatic improvement has been observed. Some patients failed to benefit from *β*-chloroethyl amine therapy. Varied responses have been observed in acute and subacute leukemias. In a considerable portion of terminal and radiation resistant cases, especially of Hodgkin's disease and lymphosarcoma, the *β*-chloroethyl amines have produced clinical remissions lasting from weeks to months. Responsiveness to radiation therapy may occasionally be restored after a course of nitrogen mustard therapy. These authors maintain that the margin of safety in the use of these chemicals is narrow, necessitating the exercise of caution. The blood picture must be carefully followed as a guide to subsequent dosage. The more serious late toxic effects are those of leukopenia, granulocytopenia, thrombocytopenia and anemia. It is not known whether the *β*-chloroethyl amines represent the best compounds of their chemical group.

Jacobson and his co-workers[3] report the results of the use of methyl-*bis*(beta-chloroethyl)amine hydrochloride in the treatment of a series of 59 patients with neoplastic and allied diseases of the hemopoietic system. In their experience acute leukemia and multiple myeloma did not respond to treatment, and the encouraging results have been largely confined to Hodgkin's disease. The common symptoms of fever and malaise were frequently relieved within a short period after the initiation of treatment. Lymphadenopathy, splenomegaly and hepatomegaly usually regressed rapidly. Repeated courses of treatment with the drug have produced further remissions. In certain cases of Hodgkin's disease classified as x-ray resistant, significant clinical remissions have been produced.

ApThomas and Cullumbine[4] treated 21 patients with Hodgkin's disease in the advanced stage and 4 patients with other reticuloses. The most important toxic effect observed was leukopenia, most cases showing this within three to twenty days of treatment. The results when compared with those of radiotherapy showed that the improvement in general condition, the lymph nodes and other signs was produced more quickly with nitrogen mustard than with x-rays but was of shorter duration. Vomiting is more likely and more severe after nitrogen mustard than after radiotherapy. There is no skin or mucosal reaction with intravenous nitrogen mustards, but local thrombosis at the injection site has been noted in a few cases. Leukopenia is certain and sometimes severe after nitrogen mustard, whereas after radiotherapy it occurs only when extensive areas are treated and can be controlled by stopping treatment. They conclude that nitrogen mustards are useful in the palliative treatment of extensive Hodgkin's disease. The symptoms can still be relieved by nitrogen mustards in cases in which radiotherapy has been abandoned.

It appears that so far these newer substances, like irradiation, have failed to cure Hodgkin's disease. However, the beneficial action already noted is of great importance, for hundreds of variants await synthesis and evaluation and it is probable that a substance will be developed which will have a more selective action on the tissues with less toxic effect.

Current Comment

DR. WINGATE JOHNSON ELECTED TRUSTEE

At its session held in Chicago September 4, the Board of Trustees of the American Medical Association elected Dr. Wingate M. Johnson, professor of clinical medicine at Bowman Gray School of Medicine of Wake Forest College, Winston-Salem, N. C., a member of the Board of Trustees to fill the unexpired term of the late Dr. Charles W. Roberts, who died in Atlanta, Ga., July 28. Dr. Wingate M. Johnson is widely known to the medical profession in the United States as one of the leaders in the field of internal medicine. He has practiced in Winston-Salem almost continuously since his graduation from Jefferson Medical College in 1908. Dr. Johnson has been a president of the North Carolina State Medical Association and also of the American Geriatrics Society. He is editor of the North Carolina State Medical Journal and author of many monographs and articles. Of late he has devoted himself increasingly to raising the status of the general practitioner, and he has served as chairman of the Section on General Practice of the American Medical Association.

REACTIONS TO BACTERIAL ANTIGENS

Elsewhere in this issue (page 94) is a report of the Council on Pharmacy and Chemistry entitled "An Inquiry into the Significance of the Tissue Reactions Caused by Antigens," by Dr. William E. Ehrich. This interesting report describes reactions in the regional lymph nodes, the general vascular system and the vital organs which may follow injection of bacterial antigens. The beneficial physiologic responses of active immunization are shown to merge, with dosages above optimal, into reactions indicating toxicity. Currently recommended dosages of bacterial vaccines (typhoid-paratyphoid 3.75 billion bacilli per course, pertussis 70-100 billion bacteria per course) may be close to the borderline between optimal immunizing and toxic quantities as estimated from the experimental results presented by Ehrich and from clinical observations. The efficacy and desirability of proper immunization procedures are unquestionable and are borne out by extensive experiences within the armed services during the war. Optimal quantities can readily be exceeded, and the systemic response in vascular system and organs weigh against indiscriminate use of immunization procedures. Moreover, there are grounds for believing that even currently approved vaccines may be susceptible of improvement in terms of reduced toxicity with undiminished efficacy by more intelligent separation and use of the specific immunizing antigens required. This is a goal for joint laboratory and clinical research. Active immunization is desirable in instances in which there is a real risk of exposure to infection, in which there is proved efficacy of the specific agent used as immunizing antigen, and when dosage is adequately known. The notion that a vaccine of unknown efficacy "can't hurt the patient even if it doesn't help him" is hardly tenable. The use of shotgun "catarrhal vaccines"[1] may involve harm as well as needless expense. Still other consequences of vaccination with bacteria or their products deserve consideration; these are the manifestations of allergy elicited when the patient is hypersensitive to the specific bacterial or other antigens in question. The systemic inflammatory responses of allergy closely resemble those due to primary toxicity. The many complex aspects of bacterial hypersensitivity have been ably discussed by Rich,[2] but their discussion would be beyond the scope of Dr. Ehrich's report. However, allergic reactions to bacterial vaccines as well as reactions of primary toxicity are complications that demand the use of vaccines only with specific and rational indications and in optimal dosage.

COMMERCIALISM IN MEDICINE IN MEXICO

Among the situations which strike the North American visitor peculiarly in some Latin American countries is the exploitation of the medical profession by unprincipled commercial agencies with ideals incompatible with the ethical standards of medicine as practiced in the United States. For instance, in Mexico there is an agency called "Productos Omega" which sends to every physician in Mexico a pack of forms on the cover of which there appears an illustration of a marble deskstand with two fountain pens. The printing indicates that the value of this little adornment is $40. The doctor is told that he is going to get this outfit absolutely free. All he has to do is to write twenty prescriptions for the products manufactured by "Omega" and then return to the firm the stubs of the prescriptions which indicate the name of the product prescribed, the name of the pharmacist, the name of the disease and the number of the prescription. A reference to the products of this company reveals that they are the manufacturers of some of the most extraordinary shotgun prescriptions ever introduced in medical practice. One includes tuberculin mixed with "thiocol" (potassium guiacolsulfonate) and two other ingredients. Another, a mercury preparation, is offered for all gastrointestinal complaints, including typhoid, paratyphoid, colon infections, gastroenteritis and fevers. For the ladies there is a preparation called "contraseptol," said to be useful in irrigating all the cavities, which includes seven different ingredients; a uterine sedative contains hydrastis, viburnum, sarsaparilla and what not. Several unscientific preparations against malaria are included. North American medicine has fought a continuously gaining battle against this type of deterioration of medical science ever since the creation of the Council on Pharmacy and Chemistry of the American Medical Association in 1905. In the advancement of medicine in Latin American countries one of the first steps must be the elimination of the commercialism that saps the very vitals of medical science in those countries.

Offer Use of Radioactive Isotopes to All Nations

Limited amounts of twenty radioactive tracer elements, out of the 90 odd isotopes produced in American atomic plants, have been offered by the United States to all nations to assist in the war on disease. President Truman announced in a telegram to the Fourth International Cancer Research Congress at St. Louis. Mr. Truman explained that the tracer elements had been made available for limited distribution to research workers in other countries. He termed the project an expression of "greater international cooperation in the field of medical and biologic research." The Atomic Energy Commission simultaneously announced that no atom bomb secrets would be endangered, stating that none of the tracers offered for sale are applicable to the development of atomic energy for industrial or military purposes. A condition of the offer is that all discoveries of foreign research workers through use of the isotopes would have to be reported freely to all nations

Study of Effect of Atom Bombing on Human Beings

The Atomic Energy Commission and the National Research Council will jointly continue long-range studies of the effect of atomic bombings on human survivors of the Nagasaki and Hiroshima attacks. A group has been assigned to this work as a result of a directive by President Truman, who authorized the council "to undertake a continuing study of the medical and biologic effects of the atomic bomb on man." Dr. Thomas M. Rivers of the Rockefeller Institute for Medical Research is chairman; the members are: Drs. George Beadle, California Institute of Technology; Detlev W. Bronk, National Research Council; Austin M. Brues, Argonne National Laboratory; George M. Lyon, chief, Radioisotope Research Section, Veterans Administration; Shields Warren, Harvard Medical School; Stafford L. Warren, University of California; George H. Whipple, University of Rochester, and Raymond E. Zirkle, University of Chicago. Dr. Lewis H. Weed, chairman of the National Research Council's division of medical sciences, said that major studies will be undertaken in genetics and heredity. Those taking part will be: Drs. H. J. Muller, Nobel prize winner, University of Indiana; L. H. Snyder, Ohio State University; James V. Neel, University of Michigan; C. H. Danforth, Stanford University, and D. R. Charles, University of Rochester.

MacArthur Reports Socialized Medicine Is Not Planned by U. S. for Japan

The War Department disclosed that General MacArthur had denied allegations by Representative Harness of Indiana, chairman of a House Expenditures subcommittee studying propaganda, that a government mission was going to Tokyo "committed in advance to a national program for socialized medicine in Japan." The general stated that "no socialization of medicine is at issue and nothing of propaganda is involved." He said that the Japanese government had asked for American advice on social security measures and the purpose of the United States was to give it.

Navy Launches Program to Reduce Venereal Disease

Coincident with reports from Italy that the U. S. Army is endeavoring to reduce its high venereal disease rate there, the U. S. Navy Potomac River Command announced a program to continue cutting down the disease rate here. The monthly rate per thousand in the District of Columbia is reported as being 34 in April, 34.67 in May, 38.28 in June and 34.93 in July. Reports from Leghorn, Italy, state that the July rate there was 240 cases per thousand men as compared with 350 per thousand in January.

Cancer Institute Announces Educational Drive

The National Cancer Institute has announced that it is about to launch a $1,250,000 program of cancer education in medical schools and other institutions. Grants will be made to institutions having cancer educational programs approved by the National Advisory Cancer Council. The purpose is to improve and integrate cancer instruction in medical schools. Grants will range from $10,000 to $25,000 and later will be made to dental schools on a lesser scale. Surgeon General Thomas Parran claims that medical students have received too little instruction in the field of cancer.

Coming Medical Meetings

Conference of State Medical Society Secretaries and Editors, Chicago, A.M.A. Headquarters, Nov. 7-8. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

American Academy of Neurological Surgery, Colorado Springs, Broadmoor Hotel, Oct. 9-11. Dr. T. C. Erickson, 1300 University Ave., Madison 5, Wis., Secretary.

American Academy of Ophthalmology and Otolaryngology, Chicago, Palmer House, Oct. 12-17. Dr. W. L. Benedict, 102 Second Ave. S.W., Rochester, Minn., Secretary.

American Anti-Arthritis Association, Del Mar, Calif., Oct. 4-5. Dr. Robert T. Pottenger, 65 N. Madison Ave., Pasadena, Calif., Secretary.

American Clinical and Climatological Association, Colorado Springs, Oct. 13-15. Dr. James Bordley III, Johns Hopkins Hospital, Baltimore 5, Secretary.

American Hospital Association, St. Louis, Sept. 22-25. Mr. George P. Bugbee, 18 E. Division St., Chicago, Exec. Secretary.

American Public Health Association, Atlantic City, Oct. 6-10. Dr. Reginald M. Atwater, 1790 Broadway, New York 19, Executive Secretary.

American Roentgen Ray Society, Atlantic City, Sept. 16-19. Dr. H. Dabney Kerr, University Hospitals, Iowa City, Secretary.

American Society for the Study of Arteriosclerosis, Chicago, Hotel Knickerbocker, Nov. 2-3. Dr. O. J. Pollak, Wilmington General Hospital, Wilmington 14, Delaware, Secretary.

American Society of Clinical Pathologists, Chicago, Drake Hotel, Oct. 28-30. Dr. A. S. Giordano, 531 N. Main St., South Bend, Ind., Secretary.

[illegible] Medical Colleges, Sun Valley, Idaho, Oct. 27- [illegible] 5 S. Wabash Ave., Chicago, Secretary.

[illegible] Association, Galveston, Texas, Oct. 17-18. Dr. William C. Menninger, 3617 W. Sixth Ave., Topeka, Kans., Secretary.

Colorado State Medical Society, Denver, Shirley-Savoy Hotel, Sept. 17-20. Mr. Harvey T. Sethman, 1612 Tremont Place, Denver 2, Executive Secretary.

Connecticut Clinical Congress, New Haven, Sept. 16-18. Dr. Francis G. Blake, 258 Church St., New Haven, Chairman.

Delaware, Medical Society of, Wilmington, Oct. 13-15. Dr. John F. Hynes, Memorial Hospital, Wilmington, Secretary.

District of Columbia, Medical Society of the, Washington, Hotel Statler, Oct. 6-8. Mr. Theodore Wiprud, 1718 M Street N.W., Washington 6, Secretary.

Indiana State Medical Association, French Lick, Oct. 28-30. Mr. Ray E. Smith, 23 E. Ohio St., Indianapolis 4, Executive Secretary.

International College of Surgeons, U. S. Chapter, Chicago, Palmer House, Sept. 29-Oct. 2. Dr. Louis J. Gariepy, 16401 Grand River Ave., Detroit 27, Secretary.

Inter-State Postgraduate Medical Association of North America, St. Louis, Public Auditorium, Oct. 14-17. Dr. Tom B. Throckmorton, 406 Sixth Ave., Des Moines, Iowa, Secretary.

Kansas City Southwest Clinical Society, Kansas City, Mo., Municipal Auditorium, Oct. 6-9. Mr. E. Leas Clower, 630 Shukert Bldg., Kansas City 6, Executive Secretary.

Kentucky State Medical Association, Louisville, Sept. 29-Oct. 2. Dr. P. E. Blackerby, 620 S. Third St., Louisville 2, Secretary.

Michigan State Medical Society, Grand Rapids, Pantlind Hotel, Sept. 23-26. Dr. L. Fernald Foster, 2020 Olds Tower, Lansing 8, Secretary.

Mississippi Valley Medical Society, Burlington, Iowa, Oct. 1-3. Dr. Harold Swanberg, 510 Maine St., Quincy, Ill., Secretary.

New England Postgraduate Assembly, Boston, Copley-Plaza Hotel, Oct. 29-31. Dr. Leroy E. Parkins, 8 Fenway, Boston 15, Chairman.

New York State Association of Public Health Laboratories, Albany, Nov. 7. Miss M. B. Kirkbride, New Scotland Ave., Albany 1, Secretary.

Pennsylvania, Medical Society of the State of, Pittsburgh, Hotel William Penn, Sept. 15-18. Dr. Walter F. Donaldson, 500 Penn Avenue, Pittsburgh 22, Secretary.

Southern Psychiatric Association, Birmingham, Ala., Oct. 13-14. Dr. Newdigate M. Owensby, 384 Peachtree St. N.E., Atlanta, Ga., Secretary.

Southwestern Medical Association, Phoenix, Ariz., Hotel Westward Ho, Nov. 6-8. Dr. Louis W. Breck, 116 Mills St., El Paso, Texas, Secretary.

Vermont State Medical Society, Burlington, Hotel Vermont, Oct. 1-3. Dr. Theodore H. Harwood, 128 Merchants Row, Rutland, Secretary.

Virginia, Medical Society of, Roanoke, Oct. 13-15. Miss Agnes V. Edwards, 1200 E. Clay St., Richmond 19, Secretary.

Washington State Medical Association, Seattle, Olympic Hotel, Sept. 28-Oct. 1. Dr. Harold E. Nichols, 327 Cobb Building, Seattle, Secretary.

Wisconsin, State Medical Society of, Milwaukee, Hotel Schroeder, Oct. 6-8. Mr. Charles H. Crownhart, 110 E. Main St., Madison 3, Secretary.

World Medical Association, Paris, France, Sept. 17-20. Dr. Charles Hill, B. M. A. House, Tavistock Sq., London, W. C. 1, England, and Dr. P. Cibrie, 60 boulevard de Latour-Maubourg, Paris 7e, France, Joint Secretaries.

GOVERNMENT SERVICES

ARMY

MEDICAL CORPS RESERVE OFFICERS' TRAINING CORPS (ROTC)

The Surgeon General has announced that Medical Corps ROTC units will be in operation at forty-three approved medical schools during the 1947-1948 academic year. This is more than double the number that were in operation during the 1946-1947 academic year. The Surgeon General plans to arrange with the remaining approved medical schools during the next year for the establishment of units in the fall of 1948. It is hoped that the goal of a unit in every approved medical school will be realized by the beginning of the 1948-1949 academic year.

The program is a procurement objective for the Reserve and Regular Army components of the Medical Department. Several hundred graduates are required on a yearly basis to build up an effective organized reserve corps in the interest of the national security program.

The program of instruction consists of two courses: an elementary course given during the freshman and sophomore academic years and an advanced course given during the junior and senior years at a rate of one hour of instruction per week throughout the four academic years. In addition, the student must agree to complete a six week summer training period in any summer following the sophomore academic year.

The instruction is designed to give the student progressive knowledge of the Army in general and the Medical Department in detail, together with the essentials of the complex problems of military preventive medicine. On satisfactory completion of the program, the young Reserve first lieutenant should, on mobilization day, be capable of taking care of himself in the Army and performing the functions of a general duty medical officer. Should he if on active duty be assigned to a troop unit, he must be given further training.

Medical Corps officers of the Regular Army are detailed to the schools as professors of military science and tactics of the ROTC units. The War Department General Staff has approved a policy of the Surgeon General to allow these PMS&Ts to participate in the graduate professional specialty training at the schools concerned.

The postwar Regular Army requires several hundred specialists certified by the various American specialty boards. Of this number, the Army graduate professional program of the Medical Department will produce about 50 per cent during the next few years. Therefore the Medical Department must take advantage of approved civilian facilities to augment requirements. Accordingly, the forty-three schools have made training available in a residency, a fellowship or on a postgraduate course basis. It is hoped to place this arrangement on a permanent basis.

The forty-three schools with the specialties indicated are as follows:

University of Arkansas School of Medicine	Obstetrics & gynecology
Baylor University College of Medicine	Internal medicine
University of Buffalo School of Medicine	Internal medicine
University of California Medical School	Psychiatry
University of Chicago School of Medicine	Psychiatry
University of Cincinnati College of Medicine	Psychiatry
University of Colorado School of Medicine	Psychiatry
Cornell University Medical College	Internal medicine
Duke University School of Medicine	Dermatology
Georgetown University School of Medicine	Internal medicine
University of Georgia School of Medicine	Radiology
George Washington University School of Medicine	Pathology
University of Illinois College of Medicine	Allergy
Indiana University School of Medicine	Cardiology
State University of Iowa College of Medicine	Thoracic surgery
Jefferson Medical College of Philadelphia	Internal medicine
Johns Hopkins University School of Medicine	Public health
University of Louisville School of Medicine	General surgery
Loyola University School of Medicine	Internal medicine
Medical College of Virginia	Internal medicine
University of Michigan Medical School	Obstetrics & gynecology
University of Minnesota Medical School	Anesthesiology
University of Nebraska College of Medicine	Orthopedic surgery
New York Medical College	Internal medicine
Ohio State University College of Medicine	General surgery
University of Oklahoma School of Medicine	Orthopedic surgery
University of Oregon Medical School	Internal medicine

THREE DAY MEDICAL ROTC CONFERENCE

Medical Corps officers who will serve as professors of military science and tactics in the Reserve Officers' Training Corps program in forty-three approved medical colleges during the coming school year attended a three day orientation conference August 27-29 in the Office of the Surgeon General. Medical students in leading educational institutions of the country will receive intensive training in military medicine through the tutelage of these Medical Corps officers, who will hold the rank of either major, lieutenant colonel or colonel.

Participating in the three day orientation conferences were representatives of the Surgeon General's Office, Army Ground Forces, G-3 or Organization and Training Division of the General Staff and the surgeons of the six Army areas.

ROTC training will be compulsory for freshmen and sophomore students in about one third of the forty-three medical colleges, mainly land grant institutions. In the others it will be voluntary. The medical officers who give the instruction to the medical students will also receive training themselves through residencies, fellowships and postgraduate work in the special fields of medicine and surgery at the respective institutions to which they are assigned.

VENEREAL DISEASE RATE LOWEST SINCE VJ DAY

The War Department has announced that the Army's venereal disease rate both at home and abroad has reached a postwar low. The venereal disease incidence rate in Europe is 23 per cent below the July 1946 high, is 50 per cent below the high rate in the Pacific in October 1946 and is 47 per cent below the April 1946 peak in the United States. Since the stringent regulations outlined by the Secretary of War last January, a sharp drop has occurred in venereal disease, and the War Department Venereal Disease Control Council, comprised of ranking members of the general and special staffs, has met periodically to survey the situation and to develop further measures for venereal disease control.

MEDICAL DEPARTMENT PERSONNEL TO SHARE IN WALTER REED MEMORIAL

Members of the Medical Department of the Army will have the opportunity to share in the honor of placing a bust of the late Major Walter Reed in the New York University Hall of Fame, the Surgeon General has announced. Although a few individual doctors requested the privilege of contributing the funds for this purpose, estimated at about $6,000, all members of the Medical Department will be given an opportunity to contribute to this fund if they desire.

Ceremonies observing the occasion will be held during the fourth International Congresses of Tropical Medicine and Malaria in Washington, D. C., May 10-18, 1948, at which time the British also will pay honor to their great malariologist Sir Ronald Ross.

NAVY

NAVAL MEDICAL RESEARCH INSTITUTE IN CAIRO

Commander Robert A. Phillips (MC), U.S.N., has been assigned to command the U. S. Naval Medical Research Unit in Cairo, Egypt. Commander Phillips went to Cairo in 1945 with the United States Typhus Commission and later to Dachau, Germany. He formerly did "faculty service" at Yale, Stanford, Harvard and Cornell universities. His first naval assignment was in 1940 at Pensacola, Fla.; later he served with the naval medical unit at Rockefeller Institute, New York.

Three American authorities on mosquito eradication left Cairo recently for the Kharga and Dekhla oases to study technical problems of malarial control in those areas. They are Dr. John M. Weir of the Rockefeller Foundation, D. C. C. Deonier of the U. S. Department of Agriculture, now on loan to the Naval Research Unit in Egypt, and Ensign C. E. Connell, who is attached to the Naval Research Unit. Egyptian health officials accompanied this group to the oases.

ANNAPOLIS HOSPITAL RECEIVES AWARD FOR SAFETY

The U. S. Naval Hospital at Annapolis, Md., on August 27 was given the Secretary of the Navy's Award for Achievement in Safety for the years 1945-1946. The award read as follows: The Secretary of the Navy's Award for Achievement in Safety is given to the Naval Hospital, Annapolis, Md., for a frequency rate of 0.00 for the years 1945 and 1946. This perfect record for two consecutive years indicates constant vigilance, enthusiastic and wholehearted cooperation, and untiring effort among all personnel. The Naval Hospital is highly commended for the establishment and maintenance of an adequate and workable safety program, which is necessary in order to maintain this low frequency rate. The Secretary's Award for Achievement in Safety is presented in grateful acknowledgment for the saving of human life, the reduction in government expenditures and the increased production which this low frequency rate signifies.

PHYSICIANS PILOT SURGEON GENERAL ON INSPECTION TRIP

Rear Admiral Clifford A. Swanson, Surgeon General of the Navy, on August 20 flew to Norfolk, Va., to inspect the Hospital Corps School at Portsmouth. The pilot and the copilot Commander N. L. Barr (MC) and Capt. B. Groesbeck Jr. are both navy doctors. Others in the plane were Rear Admiral A. W. Chandler (DC), assistant chief, Bureau of Medicine and Surgery for Dentistry; Capt. B. W. Hogan (MC), executive officer, U. S. Naval Hospital, Bethesda, Md., and Lieut. Commander A. H. Nelson (HC), administrative assistant to the Surgeon General. Following inspection of the school the Surgeon General addressed all the medical personnel at the Portsmouth Naval Hospital.

PERSONAL

Captain Harold J. Bowen (MC), U.S.N., has been assigned as chief of surgery at the Charleston naval hospital, Charleston, S. C. Following his recent war service in the Pacific area Captain Bowen did postgraduate work at Mayo Clinic, Rochester, Minn.

PUBLIC HEALTH SERVICE

PHARMACY SECTION ESTABLISHED

A new pharmacy section has been established in the Hospital Division of the U. S. Public Health Service for the further development of pharmaceutical activities in the Marine Hospitals and their adjunct medical relief stations. The new pharmacy service will be under the direction of George F. Archambault, graduate and former faculty member of the Massachusetts College of Pharmacy, who for a year was director of professional relations in the New England states for the Liggett Drug Company and during the war was chief pharmacist at the Boston Marine Hospital.

The Hospital Division of the Public Health Service has the responsibility of providing medical, dental and hospital services for American merchant seamen, members of the Coast Guard and their dependents, the Coast and Geodetic Survey, foreign merchant seamen and others designated by law. It provides this service primarily through its system of twenty-four Marine Hospitals and 115 medical relief stations located throughout the United States and its possessions.

A further important development in connection with this program is a plan for commissioning a limited number of pharmacy-college graduates every year in the Public Health Service Commissioned Reserve Corps, selecting such men as have demonstrated special interests and abilities for careers in the public health field. Already an active recruiting campaign for pharmacists to be placed on commissioned status has been conducted by the Public Health Service, the first such recruitment for pharmacists since 1930. From the resulting list the first appointments are to be made of pharmacists to serve as commissioned officers in the regular corps of the Public Health Service.

FIRST FEDERAL GRANTS FOR RESEARCH IN MENTAL HEALTH

The Surgeon General of the U. S. Public Health Service has announced the award of the first federal grants for research in mental health under the new National Mental Health Act. Under this authorization the mental health program received its first appropriation totaling $7,500,000 on July 8, which will be used to finance, in addition to paying the cost of mental health activities within the Public Health Service, a threefold program of research and development of local mental health facilities and the training of mental health personnel. The award of the first federal grants announced for this purpose will go to institutions and individuals. The grants awarded were recommended by the National Mental Health Advisory Council, which is composed of experts in the field of mental health.

MISCELLANEOUS

SALE OF SURPLUS GOVERNMENT PROPERTY

The War Assets Administration has announced the following sales of surplus government property:

The Regional Office, 30 Van Ness Avenue, San Francisco 2, is having a sale of drugs and of hospital and laboratory supplies. The closing date for bids is September 19. Awards in this sale will be made to the highest bidder without regard to the priority status. Among the items for sale are hospital beds, bedside tables, sterilizers, medicine cabinets, splints and rubber gloves.

A fixed price sale of medical, dental and x-ray equipment is being conducted. Orders must be received at the W. A. A. Customer Service Center, Bldg. T-2, ORD, East Bessemer Avenue and South 9th Street, Greensboro, N. C., before 5 p. m., September 16. This sale is for World War II veterans only and includes such items as x-ray field equipment, cassettes, film holders, dental chairs, lathes and engines, cystoscopes and dental aspirating units.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

CALIFORNIA

Refresher Courses for Physicians.—The University of California School of Medicine will present medical refresher courses for graduates of approved medical schools on the Los Angeles campus during the fall and winter months. Courses will be available in mid-September in dermatology, gynecology, medicine, general surgery, cardiology and pediatrics. Visiting lecturers scheduled to come to the Los Angeles campus include Drs. S. Charles J. Imperatori, New York; Erik Ask-Upmark, University of Upsala, Sweden; Ignacio Chavez of Mexico, D. F.; Tinsley R. Harrison, Dallas, Texas; Isadore Snapper, New York; Paul White, Boston; Frank E. Adair, New York; J. Dewey Bisgard, Omaha; Frederick A. Coller, Ann Arbor, Mich., and Ferdinand R. Schemm, Great Falls, Mont.

Dr. Stafford Warren to Head Radiation Laboratory.—The Medical School on the Los Angeles campus of the University of California will begin operating an atomic radiation medical laboratory about October 15. Research to discover means of treating radiologic injury to human beings will be the fundamental function of the new laboratory, which the university will maintain and staff under contract with the U. S. Atomic Energy Commission. The starting point for laboratory studies will be medical data collected after the bombing of Hiroshima and Nagasaki and the Bikini A-bomb tests. The laboratory will be under the direction of Dr. Stafford L. Warren, whose close connection with the A-bomb development began with his appointment as medical director of the Manhattan project in 1943. He was in charge of the first radiologic survey parties that entered the devastated Japanese cities. Between 30 and 40 persons will be involved in the laboratory project in its initial stages. Dr. Warren was appointed dean and professor of biophysics at the Los Angeles campus of the University of California early this year (The Journal, Feb. 8, p. 412). He was formerly on the faculty of the University of Rochester School of Medicine and Dentistry, Rochester, N. Y., as an associate professor of medicine in charge of radiology from 1925-1940, when he was made professor of radiology.

DISTRICT OF COLUMBIA

Impostor Repeats.—A promise to cure cancer of the breast for $1,200 is reported to have brought "Prof." Bernard Rubin, 68, of the 1600 block, Columbia Road N.W., a $100 fine and ninety days in jail when he was found guilty of practicing medicine without a license July 30 in Municipal Court in Washington, according to the Washington *Times-Herald.* Last March Rubin was fined $75 and sent to jail for sixty days for illegally practicing medicine, and in 1931 he was put on probation for petty larceny.

Georgetown University Hospital Opens.—Georgetown University's new $3,600,000 hospital opened early last month. Present at the ceremonies were the Very Rev. Lawrence C. Gorman, S. J., president of Georgetown University; the Rev. Paul A. McNally, S. J., dean of the university's medical school, and Sister Mary Antonella of the Sisters of Charity of Nazareth, superior and administrator of the new hospital. Formal dedication will not take place until this fall. The new hospital contains 407 beds and 123 bassinets, thirteen operating rooms, six delivery and labor rooms and a nursery. Its construction took thirty-one months. The hospital has been placed under the direction of the Sisters of Charity of Nazareth. The old Georgetown hospital will be used as a dormitory for Georgetown University.

ILLINOIS

State Toxicologic Analytic Service.—Establishment of a toxicologic analytic service at the University of Illinois College of Medicine, Chicago, for law enforcing agencies of the state has been announced by Dr. Carl C. Pfeiffer, head of the department of pharmacology and toxicology (The Journal, August 9, p. 1251). Dr. Pfeiffer said that the university laboratory would perform toxicologic analyses of the organs of any person whose death was unexpected. The service will be extended to all state's attorneys and coroners in the fifty-two counties of Illinois. The service has been developed as a result of numerous requests received by the University of Illinois from law enforcing agencies. State's attorneys and coroners have pointed out that facilities for accurate diagnosis of death due to poisoning are inadequate at present. Services to be performed by the university include the determination of blood alcohol, barbiturates, heavy metals, blood carbon monoxide and alkaloid tests and a complete analysis in the event that the cause of death is unknown. A nominal fee will be charged. A member of the professional staff of the department of pharmacology and toxicology will appear as an expert witness when needed. The service will be similar to a state plan already used in Michigan, Indiana and Wisconsin.

Chicago

First Cancer Research Fellowship.—Through the University of Chicago Cancer Research Foundation the university has established its first cancer research fellowship. Walter Schwimmer, Chicago advertising executive, has given the foundation $2,500 for the Daisy Schwimmer Fellowship in honor of his late wife. The research fund will be renewed for five years at $2,500 annually.

Improve Sanitation in Eating Places.—Since the city council in January authorized the board of health to hire three additional supervisors and twenty-eight additional inspectors, eighty-seven Chicago restaurants closed voluntarily while needed sanitary corrections were made. Over 6,000 food handlers have taken the four hour course in food handling and hygiene offered by the board of health. A new city ordinance, which became effective August 1, lays down more stringent rules for food dispensing establishments than were provided previously.

LOUISIANA

Narcotic Violation.—The Bureau of Narcotics, Washington, D. C., advises that Dr. Henry R. Officer, Sugartown, pleaded guilty in the U. S. District Court at Alexandria, July 24, to violation of the internal revenue code and was fined $5,000. Dr. Otto L. Freeman, Basile, who pleaded guilty in the same court July 21 to violation of the internal revenue code, was placed on probation for a period of five years. The court also fined him $2,500.

American Academy of General Practice.—A branch of the American Academy of General Practice was organized in Alexandria July 13. The aims and objective of the academy are to fulfil among general practitioners the same functions as are performed for physicians and surgeons by the American Academy of Physicians and Surgeons, to revise the standards of general practice and to bring greater recognition of the general practitioner. The following officers were elected: Drs. Jason P. Sanders, Shreveport, president; Guy R. Jones, Lockport, president-elect; Dorman B. Barber, Alexandria, vice president; Harry P. Forsyth, Alexandria, secretary, and Johnnie W. Atkinson, Gretna, treasurer.

MASSACHUSETTS

Graduate Course in Pediatrics.—Harvard Medical School, Boston, will hold a two week course, six hours daily, in diagnosis, therapy and prevention of diseases of infants, children and adolescents at the Massachusetts General Hospital, Boston, October 13-24. The course will cover growth and development, nutrition, endocrinology, metabolic and infectious diseases, allergy, cardiology, surgery, neurology and psychiatry. For information, address Course for Graduates, Harvard Medical School, Boston.

Medicolegal Conference.—The departments of legal medicine of the medical schools of Harvard, Tufts and Boston University and the Massachusetts Medico-Legal Society will present a six day program of lectures, conferences and demonstrations concerning the investigation of deaths in the interest of public safety October 13-18, at Harvard. Attendance will be limited to 25 persons who have registered in advance. Information may be obtained from the Department of Legal Medicine, 25 Shattuck Street, Boston.

MISSOURI

Dr. Post Awarded Howe Medal.—Dr. Lawrence T. Post, head of the ophthalmology department, Washington University School of Medicine, St. Louis, was recently awarded the Lucien Howe medal of the American Ophthalmological Society at its annual meeting at Hot Springs, Va. The award was in recognition of Dr. Post's work in teaching and for leadership in the study of eye diseases. Dr. Post, a graduate of Johns Hopkins University, 1913, is a member of the National Research Council's Subcommittee on Ophthalmology and serves on the staffs of a number of St. Louis hospitals.

NEW YORK

Dr. Roberts Retires.—Dr. Bertrand E. Roberts, Poughkeepsie, after twenty-five years' service in the New York State Department of Health, retired July 23. He has been associated with the department since 1922, first as epidemiologist and for the past seventeen years as district state health officer in charge of the Poughkeepsie area. He was health officer and city bacteriologist of Oskaloosa, Iowa, in 1916.

Four Hundred Fifty Year Practitioners. — Over 400 New York physicians who have practiced medicine for fifty years or more have been given commemorative certificates by the Medical Society of the State of New York. Dr. Nathan B. Van Etten, 300 East Tremont Avenue, Bronx 57, New York, has been named chairman of the organization committee for the suggested Fifty Year Club of New York State.

New York City

Dr. Friedman Retires.—Dr. Emanuel D. Friedman, chairman of the department of neurology, New York University College of Medicine, retired September 1 after thirty-seven years' service at the college and will become professor emeritus. A graduate of New York University College of Medicine, 1907, he has taught continuously since 1913 He became successively instructor in neuropathology in 1919, lecturer in neuropathology in 1922, clinical professor of neurology in 1924 and professor of neurology and head of the department in 1927. Of his various hospital staff appointments in New York and New Jersey, he will retain that of neuropsychiatrist to the psychiatric division at Bellevue Hospital.

Dr. Peterson to Go to China for WHO.—Dr. Jerome S. Peterson, district health officer of the New York City Department of Health, returned to China September 1 to serve a year as epidemiologist for the World Health Organization. He has been granted leave of absence. His work will be mainly concerned with the study and control of cholera, bubonic and pneumonic plague and kala-azar. A graduate of Columbia University College of Physicians and Surgeons, New York, 1931, Dr. Peterson joined the New York Health Department in 1937 and has been a health officer since 1942 For ten months last year he served with the United Nations Relief and Rehabilitation Administration as chief medical officer in China, where he had previously studied cholera.

OHIO

Society News.—The new officers for the Ohio State Radiological Society for 1948 are Dr. Ralph W. Holmes, Chillicothe, president; Henry Snow, Dayton, vice president, and Carroll C. Dundon, Cleveland, secretary-treasurer. The society will meet in conjunction with the Ohio State Medical Association in Cincinnati in May 1948.

Dr. Jordan Joins Cleveland Clinic Staff.—The Cleveland Clinic is expanding its educational activities, with particular emphasis on postgraduate medical training. The increased number of graduate fellowships offered by the clinic since the end of the war in connection with the G. I. Bill requires an augmented educational program of fellowship training. Also the Bunts lecture courses for practicing physicians will be given added importance. In connection with this program the Cleveland Clinic Foundation has added Dr. Edwin P. Jordan, Chicago, to its staff. Dr. Jordan will be director of medical education and the Bunts Educational Institute—the latter a newly created position which will correlate all of the educational activities of the Cleveland Clinic. This will include also the editorial, library, photographic and art departments of the clinic.

OKLAHOMA

Postgraduate Circuit Begins September 22.—The Postgraduate Committee of the Oklahoma State Medical Association has announced that teaching circuit number four, covering Kay, Noble, Pawnee, Osage, Payne, Lincoln, Creek and Tulsa counties, will open September 22. The committee has reported that the incidence of attendance at meetings in the first three circuits has averaged 87 per cent of those enrolled. Teaching centers in the fourth circuit will be Ponca City, Pawhuska, Stillwater-Cushing, Bristow-Sapulpa and Tulsa. The course of instruction will be in gynecology and will extend over a period of ten weeks.

Personals.—Dr. McLain Rogers, Clinton, was appointed acting superintendent of the Western Oklahoma Tuberculosis Sanatorium at Clinton, effective June 23. Dr. Rogers is a graduate of Atlanta (Ga.) College of Physicians and Surgeons, 1902, and is a member of the American College of Surgeons.——At the recent Rotary Convention in San Francisco Dr. Ralph C. Meloy, Claremore, was elected governor of the 136th District of Rotary International and as such will visit the fifty-nine Rotary clubs of Arkansas, Kansas, Missouri and Oklahoma during the next twelve months. Dr. Meloy is a past president of the Rogers County Medical Society.

TEXAS

Convalescent Home for Cancer Patients.—The M. D. Anderson Hospital for Cancer Research, Houston, September 1 opened a new annex, which will house 30 ambulatory cancer patients. The two story brick building was purchased and remodeled as a gift to the Texas Medical Center, Inc., by Mr. and Mrs. Lamar Fleming Jr., Houston, at a cost of about $45,000. Other gifts from individuals and clubs total $5,000. Two types of ambulatory patients will be housed in the annex: out of town cancer sufferers during periods of examination and diagnosis and patients released from the hospital but needing postoperative care or treatment. Free patients and part pay patients will be accepted. The hospital is operated by the University of Texas.

Dallas Cerebral Palsy Center.—A Dallas treatment center for cerebral palsied children established recently by the Dallas Society for Crippled Children, and approved by the Dallas County Medical Society, is in operation to treat cerebral palsied children, educate the public, demonstrate to the medical profession the benefit of early diagnosis and treatment and carry on research. An advisory board from the medical society helped to set up standards of treatment on an outpatient basis, and the Dallas Junior League supplies financial aid and volunteer workers to assist with clerical details and the care of the children. Similar projects throughout the state with the cooperation of the medical profession will be sponsored by the Texas Society for Crippled Children.

UTAH

State Medical Meeting September 11-13.—The fifty-second meeting of the Utah State Medical Association is being held at the Union Building, University of Utah, Salt Lake City, September 11-13, under the presidency of Dr. Lester A. Stevenson, Salt Lake City. On this centennial year of the settlement of the Salt Lake Valley the program committee has invited a number of natives of Utah in prominent places in the medical world to take part in the annual meeting. They include John L. Emmett, urologist, Rochester, Minn.; A. Ray Irvine, ophthalmologist, Los Angeles; Lawrence W. Sloan, surgeon, and Thomas W. Stevenson, surgeon, both of New York. Other speakers are O. Spurgeon English, psychiatrist, Philadelphia; Louis S. Goodman, pharmacologist, Salt Lake City; C. Gordon Heyd, surgeon, New York; Albert W. Holman, obstetrician and gynecologist, Portland, Ore.; William S. Middleton, internal medicine, Madison, Wis., and Richard H. Young, Salt Lake City. Among the subjects to be discussed are recent advances in drug therapy, infection of the genitourinary tract, present status of plastic surgery, current therapeutic procedures in coronary disease and eye changes associated with thyroid disease, and hydatid mole and chorionepithelioma. There will be seminars in obstetrics, gynecology and surgery Thursday afternoon, one in phychiatry and internal medicine and another in eye, ear, nose and throat on Friday afternoon. The Woman's Auxiliary will have its annual meeting at the Hotel Utah, where the annual banquet will be held Friday evening.

WEST VIRGINIA

Heart Association Meeting.—The fall meeting of the West Virginia Heart Association will be held at the American Legion Home, Parkersburg, October 2. The case presentation and round table discussion, beginning at 2 o'clock, will be followed by a joint dinner meeting with the Parkersburg Academy of Medicine at 6:30. Dr. A. Carlton Ernstene, Cleveland, will speak at the dinner on "Curable Types of Heart Disease." Further information may be obtained from Dr. Ray H. Wharton, secretary, 955 Market Street, Parkersburg.

Dr. Hobbs to Head Department.—Dr. Milford L. Hobbs, Fairmont, has been appointed head pathologist and clinical pathologist at the West Virginia University School of Medicine, Morgantown, beginning September 1. He succeeds Dr. Clement C. Fenton, who died May 28. Dr. Hobbs, a graduate of Washington University School of Medicine, St. Louis, 1931, was assistant professor of pathology at the University of Vermont College of Medicine, Burlington, before locating in Fairmont in 1946 as pathologist at the Fairmont General Hospital.

GENERAL

Grants for Allergy Research.—The American Allergy Fund is offering a number of grants for scientific research not to exceed $3,500 each year to individual investigators. Both medical and nonmedical scientists are invited to apply for grants. Preference will be given problems immediately related to allergy, although investigations in physiology, biochemistry, pharmacology, immunology, genetics and other basic sciences are solicited. Applications should be sent to the American Allergy Fund, 525 Erie Building, Cleveland 15, Attention: Scientific Council. President of the board of the American Allergy Fund, organized a little more than a year ago, is Dr. Jonathan Forman, editor of the *Ohio State Medical Journal*, and Dr. Anton J. Carlson, University of Chicago, is head of the Scientific Advisory Council.

Fellowship Available in Rheumatic Disorders.—New York University College of Medicine and the Fourth Medical Division of Bellevue Hospital have announced the one year nonresident Robert Trubek Fellowship in Rheumatic Disorders open to graduate-physicians with at least two years of previous training in internal medicine or its equivalent. Preference will be given candidates with a background of biochemistry, biophysics or any of the basic sciences. The fellowship will combine supervised research and special clinical training in the rheumatic disorders under the direction of Dr. Otto Steinbrocker. It carries an annual stipend of $2,500, appointment renewable for an additional year by mutual agreement. Applicants for the 1947-1948 fall session should file applications not later than October 1, together with their educational and professional qualifications accompanied by two letters of recommendation from physicians under whose supervision previous assignments have been completed. Address the Robert Trubek Fellowship Committee, Fourth Medical Division, Bellevue Hospital, 492 First Avenue, New York 16.

Hospital Survey Published.—The Commonwealth Fund has published a volume on Hospital Care in the United States, which summarizes the entire findings of the intensive, two year survey of hospital facilities by the Commission on Hospital Care and lists 181 specific recommendations for the future development of hospital care in the United States. The commission estimates that there is need for an additional 195,000 general hospital beds besides the 25 per cent of existing hospital beds that are outmoded and should be replaced. It indicates that the public would be better served by about 40 per cent fewer but larger hospitals. At present building costs it would require about $1,800,000,000 to construct and equip hospitals necessary to meet the estimated current deficiency. The Commission on Hospital Care, a nongovernmental public service committee, was established in October 1944. Its purpose was to conduct the survey with particular reference to the part hospitals should play in the future life of the people. It was inaugurated by the American Hospital Association and financed by grants from the Commonwealth Fund, the W. K. Kellogg Foundation and the National Foundation for Infantile Paralysis. Full cooperation was given by the U. S. Public Health Service. Copies of the 700 page volume can be secured from the Commonwealth Fund, New York City, at $4.50 each.

Cancer Grants and Fellowships Available.—The Committee on Growth of the National Research Council, acting for the American Cancer Society, is entertaining applications for grants and fellowships. Applications for extension of existing grants in cancer research will be received until October 1, applications for new grants until November 1. Applications for fellowships and senior fellowships in cancer research may be submitted until December 1. Final decision on applications submitted during this period will be made in most cases soon after February 1. Fellowships may begin at any time determined by the committee, though ordinarily these also will take effect July 1. During the past two years the American Cancer Society, acting on the recommendation of the Committee on Growth, has awarded 176 grants and 47 fellowships representing a total expenditure of some $2,700,000. The committee will continue to recommend support of biologic and clinical research dealing broadly with phenomena relating to growth, typical or neoplastic. In the formulation of this program the committee will be guided, as in the past, by the advice of some 120 scientists grouped in twenty panels comprising its sections on biology, chemistry, physics, chemotherapy, clinical investigations and fellowships. Communications regarding grants or fellowships should be addressed to Executive Secretary, Committee on Growth, National Research Council, 2101 Constitution Avenue N. W., Washington 25, D. C.

Prevalence of Poliomyelitis.—Reports of cases of poliomyelitis for the periods indicated have been received from the division of public health methods, U. S. Public Health Service:

FOREIGN

Malaria Control in Greece.—The United Nations' World Health Organization, which is continuing malaria control measures in Greece begun by UNRRA, from January to June sprayed 15,250 Greek villages with DDT. Last year 4,005 villages received the spray treatment from UNRRA.

Typhoid in China.—A typhoid epidemic that has filled 20 per cent of the beds in four hospitals at Foochow, Fukien province capital, was reported August 16 by UNRRA's China office. The city of 350,000 has no public water supply. Seven water filtration stations are being constructed in an attempt to check the outbreak.

French Congress of Medicine.—The twenty-sixth French Congress of Medicine will be held in Paris, October 16-18, at the Faculty of Medicine under the chairmanship of Dr. André A. Lemierre, Paris. Presentation and discussion of papers on genetics will be given on Thursday, papers and discussions on antihistaminics on Friday and presentation and discussion of papers on pulmonary cysts on Saturday. Further information may be obtained from the Office of the Secretary, the Faculty of Medicine, Room Beclard, Street of School of Medicine, Paris.

Deaths

J. Bayard Clark ⊕ New York; born in Elizabeth, N. J., in 1869; Columbia University College of Physicians and Surgeons, New York, 1898; an Affiliate Fellow of the American Medical Association; fellow of the American College of Surgeons; member of the Connecticut State Medical Society and the American Urological Association; member, past president and vice president of the American Association of Genito-Urinary Surgeons; formerly professor of urology at the New York Polyclinic Medical School and Hospital; specialist certified by the American Board of Urology; served during World War I; affiliated with the Greenwich (Conn.) Hospital, Elizabeth (N. J.) General Hospital, Doctors Hospital and the New York City Hospital; author of "Some Personal Recollections of Dr. Janeway"; died May 20, aged 78, of heart disease.

Hilbert Francis Day ⊕ Cambridge Mass.; born in Boston in 1879; Harvard Medical School, Boston, 1905; professor of clinical surgery at the Tufts College Medical School in Boston; formerly on the faculty of his alma mater, past president of the Cambridge Tuberculosis and Health Association; member of the founders group of the American Board of Surgery; member of the New England Obstetrical and Gynecological Society and the New England Pediatric Society, fellow of the American College of Surgeons; on the staffs of the Boston Dispensary, Cambridge Hospital, Boston Floating Hospital, Masonic Hospital, Shrewsbury, State Prison Colony Hospital, Norfolk, and the Massachusetts Women's Hospital in Boston; died May 16, aged 68, of heart disease.

Andrew Johnson Browning, Portland, Ore.; born in Washington, D. C., in 1881; George Washington University School of Medicine, Washington, D. C., 1908; associate clinical professor of ophthalmology at the University of Oregon Medical School; specialist certified by the American Board of Ophthalmology; served as president and secretary of the Western Ophthalmological Society; member of the American Academy of Ophthalmology and Otolaryngology and the Pacific Coast Oto-Ophthalmological Society; on the staffs of the Doernbecher Memorial Hospital for Children and the Multnomah Hospital; a member of the board of trustees of the Good Samaritan Hospital, where he died May 20, aged 66.

Walter Ashby Frankland ⊕ Washington, D. C.; born in Baltimore in 1867; Columbian University Medical Department, Washington, 1896; served overseas during World War I; formerly associated with the U. S. Public Health Service; past president of the Washington Medical and Surgical Society; member of the Association of Military Surgeons of the United States; at one time on the faculty of George Washington University School of Medicine; served on the staffs of the Casualty and George Washington University hospitals, died in the U. S. Naval Hospital in Bethesda, Md., May 30, aged 79, of lobar pneumonia and arteriosclerosis.

Benjamin Jaffee Birk ⊕ Milwaukee; born in Michigan City, Ind., Aug. 17, 1894; Rush Medical College, Chicago, 1919; fellow of the American College of Physicians; member of the Association of Military Surgeons of the United States, Wisconsin Heart Association and the American Heart Association; on the staff of the Mount Sinai Hospital; served during World War I; during World War II served in the China-Burma-India theater for thirteen months and was awarded the Legion of Merit with oak leaf cluster for exceptional work in China in 1944; died in Thiensville, Wis., June 28, aged 52, of heart disease.

Harold William Campbell, Philadelphia; born in Bridgeport, Conn., April 1, 1905; University of Colorado School of Medicine, Denver, 1941; member of the American Medical Association and the Colorado State Medical Society; interned at St. Joseph's Hospital in Denver and served a residency at the Evangelical Lutheran Sanatorium in Wheat Ridge, Colo.; instructor in medicine at the University of Pennsylvania and clinic physician at the Henry Phipps Institute for the study, treatment and prevention of tuberculosis; died May 5, aged 42, of chronic nephritis.

Claude Miller Ament, Tulsa, Okla.; Barnes Medical College, St. Louis, 1901; at one time on the faculty of his alma mater; died May 10, aged 71.

Coral Ray Armentrout ⊕ Houston, Texas; Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1904; fellow of the American College of Surgeons; served during World War I; formerly on the faculty of his alma mater; on the staffs of the Memorial Hospital and St. Joseph's Infirmary; died May 3, aged 69, of heart disease.

Lewis George Babcock, San Marino, Calif.; College of Physicians and Surgeons, Los Angeles, 1921; member of the American Medical Association; died in the Huntington Memorial Hospital, Pasadena, June 5, aged 51, of acute myelogenous leukemia.

Carlos M. Balli, Monterrey, Nueva Leon, Mexico; Universidad Nacional Facultad de Medicina, Mexico, D.F., 1918; died in May, aged 59.

Cobb Rutherford Barksdale, Blakely, Ga.; University of Georgia Medical Department, Augusta, 1900; member of the American Medical Association; served as mayor and member of the city council; for many years county physician; died in the Georgia Baptist Hospital, Atlanta, May 28, aged 70, of pneumonia and carcinoma.

Charles Wallace Bassett ⊕ St. Louis; Washington University School of Medicine, St. Louis, 1908; died in Madison, N. Y., June 18, aged 72.

Oscar Israel Baumann ⊕ New York; Columbia University College of Physicians and Surgeons, New York, 1910; served during World War I; affiliated with the Mount Sinai Hospital and the Hospital for Joint Diseases; died May 17, aged 59, of coronary sclerosis with myocardial infarction.

Howell Llewellyn Begle ⊕ Detroit; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1905; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology; for many years on the staff of the Children's Hospital; served as secretary of the Michigan Association of Industrial Physicians and Surgeons; past president of the Detroit Ophthalmological Society; died June 5, aged 70.

Gertrud Behrens, New York; Christian-Albrechts-Universität Medizinische Fakultät, Kiel, Prussia, 1919; member of the American Medical Association; died May 19, aged 53.

Sanford Blum ⊕ San Francisco; University of California Medical School, San Francisco, 1896; formerly on the faculty of his alma mater; died May 27, aged 74, of heart disease.

George Washington Boner, North Madison, Ind.; Hospital College of Medicine, Louisville, Ky., 1906; member of the American Medical Association; served during World War I; formerly assistant physician at the Muscatatuck State School in Butlerville; since July 1945 superintendent of the Madison State Hospital, where he died May 30, aged 69, of coronary occlusion.

Robert Campbell Boothe, Fort Pierce, Fla.; Hospital College of Medicine, Louisville, Ky., 1905; member of the American Medical Association; member of the draft boards during World wars I and II; died May 20, aged 72, of cerebral hemorrhage.

Marcus Bossard, Spring Green, Wis.; Bellevue Hospital Medical College, New York, 1886; died May 8, aged 82, of carcinoma of the liver.

George Floyd Bott, Victor, Iowa; State University of Iowa College of Homeopathic Medicine, Iowa City, 1906; died May 7, aged 70, of coronary thrombosis.

Kent Amos Bowman ⊕ Johnstown, Pa.; Jefferson Medical College of Philadelphia, 1914; served as vice president of the Cambria County Medical Society; a medical officer in the U. S. Army during World War I; affiliated with Conemaugh Valley Memorial Hospital and Mercy Hospital, where he died June 4, aged 57, of carcinoma of the prostate with metastasis.

Harry August Brandes ⊕ Bismarck, N. D.; Washington University School of Medicine, St. Louis, 1912; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; past president of the North Dakota State Medical Association; served as a member of the state board of medical examiners; on the staffs of the Bismarck and St. Alexius hospitals; died May 12, aged 59, of multiple myeloma.

Nathaniel Perkins Breed, Douglaston, N. Y.; Harvard Medical School, Boston, 1901; died May 11, aged 70, of heart disease.

Ellen Martin Brimer, San Diego, Calif.; Gross Medical College, Denver, 1897; died May 5, aged 77.

Diedrich George Brunjes ⊕ Chicago; the Hahnemann Medical College and Hospital, Chicago, 1910; served during World War I; on the staffs of the Chicago Memorial and Illinois Central hospitals; died May 17, aged 60, of coronary thrombosis.

Edward Henry Buffum, Manchester, N. H.; Middlesex College of Medicine and Surgery, Waltham, Mass., 1937, for many years affiliated with the Nassau County Sanatorium in Farmingdale, N. Y.; died June 25, aged 44.

Joseph E. Burnham, Wayne, Ohio; Cleveland Medical College, Homeopathic, 1895; died May 21, aged 82, of coronary thrombosis.

Alton Cook Campbell ⊕ Raleigh, N. C.; University of North Carolina School of Medicine, Raleigh, 1910; served during World War I; member of the Raleigh township school board; for many years physician at the North Carolina State College; on the staff of the Rex Hospital; died June 12, aged 63.

Burg Chadwick, Smethport, Pa.; University of Buffalo School of Medicine, 1887; Jefferson Medical College of Philadelphia, 1888; member of the American Medical Association; for many years physician for the McKean County Home and the McKean County Jail; served on the staff of the Bradford Hospital; died May 8, aged 79, of carcinoma of the prostate.

Eben P. Clapp, Pasadena, Calif.; the Hahnemann Medical College and Hospital, Chicago, 1882; died in the Huntington Memorial Hospital May 8, aged 88, of bronchopneumonia and arteriosclerosis.

Walton Wheeler Cobb, Fort Worth, Texas; Kentucky School of Medicine, Louisville, 1895; past president of the Tom Green-Coke-Crockett Concho-Irion-Sterling-Sutton-Schleicher Counties Medical Society; served as city health officer of San Angelo, where he was on the staffs of the Shannon West Texas Memorial Hospital and St. John's Hospital; died in the Methodist Hospital May 17, aged 74, of uremia.

Robert Calvin Coomer, Richmond, Ky.; Kentucky School of Medicine, Louisville, 1902; member of the American Medical Association; died in the Pattie A. Clay Infirmary May 5, aged 73, of carcinoma.

Alfred G. Coughlin, Athens, Pa.; Baltimore Medical College, 1905; for many years president of the board of directors of the school district and physician for the local board of health; on the staff of the Robert Packer Hospital in Sayre; president of the Athens National Bank; director of the Athens Building and Loan Association and the chamber of commerce; died May 1, aged 63, of hypertensive cardiovascular disease.

F. W. Cox, Pocahontas, Ark. (licensed in Arkansas in 1903); died in the Baptist Hospital in Memphis, Tenn., May 8, aged 69, of heart disease.

William Nathan Crellin, Shohola, Pa.; Jefferson Medical College of Philadelphia, 1931; member of the American Medical Association; interned at the Frankford Hospital in Philadelphia; served as county medical director and as surgeon for the Erie Railroad Company; died May 5, aged 40, of injuries received when his automobile crashed against a tree near Monroe, N. Y.

George Hardin Curfman ⊕ Denver; Northwestern University Medical School, Chicago, 1905; member of the House of Delegates of the American Medical Association in 1925, 1945 and 1946; fellow of the American College of Surgeons; past president of the Colorado State Medical Society; chief surgeon for the Denver and Rio Grande Western Railroad; on the staff of St. Joseph's Hospital, where he died June 24, aged 69.

Frank Curtiss Davis, Palo Alto, Calif.; Johns Hopkins University School of Medicine, Baltimore, 1899; fellow of the American College of Surgeons; served during World War I; died May 30, aged 73, of acute cardiac failure and arteriosclerosis.

John Spencer Davis, Dallas, Texas; Medical Department of Tulane University of Louisiana, New Orleans, 1908; affiliated with St. Paul's Hospital; member of the American Medical Association; served during World War I; died recently, aged 66, of heart disease.

Dayve Boris De Waltoff, Brooklyn; University of St. Vladimira Faculty of Medicine, Kiev, Russia, 1887; died June 19, aged 81, of heart disease.

Thomas Lawrence Disque ⊕ Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1892; assistant professor of urology at his alma mater; member of the American Urological Association; on the staffs of St. Francis, Woman's and Presbyterian hospitals; died May 7, aged 76, of carcinoma of the sigmoid.

David Cummins Donan, Morganfield, Ky.; University of Louisville (Ky.) Medical Department, 1907; member of the American Medical Association; formerly secretary of the Union County Medical Society; served during World War I; colonel, medical reserve corps, U. S. Army, not on active duty; died in Our Lady of Mercy Hospital May 16, aged 65, of cerebral hemorrhage.

John Joseph Donohue, Shamokin, Pa.; Jefferson Medical College of Philadelphia, 1911; member of the American Medical Association; served during World War I; died in the Temple University Hospital in Philadelphia, May 10, aged 62.

Joseph Alexander Doyle ⊕ Greenville, Pa.; University of Pittsburgh School of Medicine, 1918; served during World War I; fellow of the American College of Surgeons; county coroner; affiliated with the Greenville Hospital; died in the Cleveland Clinic Foundation Hospital June 21, aged 56, of pneumonia following influenza.

John B. du Bose, Humble, Texas; University of Dallas Medical Department, 1902; member of the American Medical Association; died recently, aged 70, of chronic myocarditis.

H. Rolfe Du Puy, Winchester, Va.; University of Virginia Department of Medicine, Charlottesville, 1932; member of the American Medical Association; served as deputy state and county health officer of Garrett County in Maryland, health officer of Berkeley County in West Virginia and Worcester County in Massachusetts; died May 3, aged 40.

Edgar A. Farrow, San Diego, Calif.; Columbian Medical College, Kansas City, Mo., 1899; for many years affiliated with the Indian Service; veteran of the Spanish-American War; died May 7, aged 73, of coronary occlusion.

Samuel Arthur Flaherty ⊕ Detroit; Detroit College of Medicine and Surgery, 1914; member of the American Urological Association and at one time secretary of the Detroit Branch; served with the Canadian Army during World War I; on the staffs of the Mount Carmel Mercy and Delray General hospitals; died in Lake Lure, N. C., May 8, aged 60, of coronary thrombosis.

Charles George Foertmeyer, Cincinnati; Medical College of Ohio, Cincinnati, 1895; member of the American Medical Association; died in the Deaconess Hospital May 7, aged 75, of carcinoma.

A. O. Fortney, Jewell, Kan.; Missouri Medical College, St. Louis, 1894; died in Beloit May 15, aged 81, of coronary occlusion.

John Russell Foshay ⊕ Peekskill, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1909; served as a member of the county board of health and county coroner; on the staff of the Peekskill Hospital; died in Ossining June 14, aged 67, of coronary thrombosis.

Joseph Powel Franklin, Cumberland, Md.; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1921; member of the American Medical Association; deputy state and county health officer of Allegany County; formerly director of the bureau of communicable diseases, Baltimore City Health Department; served during World War I and World War II; died in the Mount Sinai Hospital, Baltimore, June 15, aged 50, of carcinoma of the liver.

Harry Edwin Gabe, Indianapolis; Medical College of Ohio, Cincinnati, 1893; member of the American Medical Association; past president of the Indianapolis Medical Society; served on the city board of health; died in the Methodist Hospital June 14, aged 79, of aneurysm.

Jacques Goldberger, New York; Magyar Kiralyi Pazmany Petrus Tudomanyegyetem Orvosi Fakultasa, Budapest, Hungary, 1911; affiliated with the Saratoga Hospital in Saratoga Springs; died in the Montefiore Hospital June 5, aged 58, of adenocarcinoma of the sigmoid colon.

Irvin Hilary Griffin ⊕ Moundville, Ala.; Tulane University of Louisiana School of Medicine, New Orleans, 1934; on the staffs of the Druid City and Stillman hospitals in Tuscaloosa; died in Tuscaloosa June 1, aged 38, of coronary thrombosis.

Harry Harold Halliwell ⊕ Ilion, N. Y.; University and Bellevue Hospital Medical College, New York, 1901; died May 11, aged 67, of hernia, embolism, fecal fistula and prostatic hypertrophy.

Clarence C. Hampil, Brazoria, Texas; Louisville (Ky.) Medical College, 1892; member of the American Medical Association; past president of the Brazoria County Medical Society; received a medal and a certificate of merit for his work with the selective service board during World War II; at one time director of the First State Bank of Brazoria; died recently, aged 79, of cerebral hemorrhage and coronary occlusion.

Raymond George Earl Haymond, Waldron, Ind.; University of Louisville (Ky.) Medical Department, 1909; served during World War I; found dead June 20, aged 69.

Cecil Marvin Hitchcock, Moultrie, Ga.; University of Georgia Medical Department, Augusta, 1906; for many years county physician; examining physician for the selective service board during World War II; on the staff of the Vereen Memorial Hospital; died June 5, aged 63, of chronic nephritis and hypertensive heart disease.

Fred Garnt Hopkins ✠ East Peoria, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905; member of the staff of the St. Francis Hospital, Peoria, of which he had been president; past president of the sanitary board: died June 14, aged 71, of leukemia.

Charles Francis Hull, Carthage, Texas; Memphis (Tenn.) Hospital Medical College, 1899; member of the American Medical Association; served as president, secretary and treasurer of the Panola County Medical Society; for many years county health officer; died recently, aged 83, of encephalomalacia and arteriosclerotic heart disease.

Otto B. Kiehl, Pittsburg, Kan ; University of Kansas School of Medicine, Kansas City, 1907; member of the American Medical Association; past president of the Crawford County Medical Society; served as city health officer; on the staff of Mount Carmel Hospital; died May 10, aged 67, of acute coronary thrombosis.

John Joseph Krager, Baltimore; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1922; died recently, aged 52, of coronary thrombosis.

John B. Marcotte, Lewiston, Me.; Laval University Faculty of Medicine, Quebec, Canada, 1899; member of the American Medical Association; affiliated with St Mary's Hospital; died recently, aged 81, of carcinoma.

Bertie Mobbs, Honolulu, Hawaii; University of Louisville School of Medicine, 1910; also a graduate in pharmacy; served on the staffs of St. Francis, Queen's and Maternity hospitals; died recently, aged 70, of aneurysm of the abdominal aorta.

Edwin Corbin Neeb, Cross Plains, Texas; Baylor University College of Medicine, Dallas, 1947, internship appointment was Charity Hospital of Louisiana at New Orleans; died May 31, aged 22, of embryonal cell carcinoma.

Leroy S. S. Ott, Longdale, Okla.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1910; member of the American Medical Association and the Kansas Medical Society; served as health officer of Wichita County, (Kan.); died May 4, aged 59, of coronary thrombosis.

Harry Milton Pell, Brazil, Ind.; Indiana University School of Medicine, Indianapolis, 1912; member of the American Medical Association; served during World War I; at various times county coroner, county jail physician and on the staff of the Indiana State Farm Hospital in Greencastle; on the staff of the Clay County Hospital, where he died May 30, aged 56, of cardiovascular renal disease.

Paul Lange Phillips, Norfolk, Va ; Cornell University Medical College, New York, 1930; member of the American Medical Association, American Psychiatric Association and the Connecticut State Medical Association; served during World War II; died May 11, aged 42, of coronary occlusion.

Oscar Ignatius Polk ✠ Pittsburgh; University of Pittsburgh School of Medicine, 1911; served as school director of the public schools of Braddock and on the staff of the Braddock (Pa.) General Hospital; died May 8, aged 59, of coronary occlusion.

Rose Pringle, New York; Trinity Medical College, Toronto, Ont., Canada, 1895; member of the American Psychiatric Association; for many years affiliated with the Bloomingdale Hospital in White Plains; died in Detroit May 9, aged 83, of heart disease.

Lenard L. Shlenker, Monroe, La.; Washington University School of Medicine, St. Louis, 1929; member of the American Medical Association; served during World War I and World War II; died May 5, aged 47, of cerebral hemorrhage.

Edward Augustine Stapleton ✠ Albany, N. Y.; Albany Medical College, 1904; also a graduate in pharmacy; served during World War I; died in the Memorial Hospital June 11, aged 66.

William Borden Thomas Jr. ✠ Amarillo, Texas; University of Tennessee College of Medicine, Memphis, 1932; health officer of Amarillo and Porter County; died May 3, aged 41, of heart disease.

Hartley W. Walker, Pekin, Ill.; Baltimore Medical College, 1895; member of the American Medical Association; served on the draft boards during World Wars I and II; on the staff of the Pekin Public Hospital; died June 5, aged 73, of coronary occlusion.

Otis Hillsman Whitlock, Richmond, Va.; University College of Medicine, Richmond, 1911; member of the American Medical Association; burned to death May 9, aged 60.

DIED WHILE IN MILITARY SERVICE

William Craig Flinn, Redwood Falls, Minn.; Harvard Medical School, Boston, 1943; interned at the Ancker Hospital in St. Paul; diplomate of the National Board of Medical Examiners; began active duty as a first lieutenant in the medical corps, Army of the United States, on Jan. 5, 1944; later promoted to captain; died in France July 7, 1945, aged 27, of a skull fracture received in a vehicle accident.

Jay Curtis Joslyn, Sandusky, N. Y.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1945; interned at the Naval Hospital in San Diego; began active duty as a lieutenant (jg) in the medical corps of the U. S. Naval Reserve on Sept. 2, 1945; died March 20, 1946, aged 24, of myelogenous leukemia.

Herman George Klamka, Chicago; University of Illinois College of Medicine, Chicago, 1940; interned at the Cook County Hospital; captain in the medical corps, Army of the United States; killed in India May 25, 1944, aged 29, in an airplane crash.

Braulio Rodriguez Martinez, Ponce, P. R.; Howard University College of Medicine, Washington, D. C., 1942; interned at the Freedmen's Hospital in Washington, D. C.; began active duty as a first lieutenant in the medical corps, Army of the United States, on July 3, 1943; died in the Fitzsimmons General Hospital in Denver April 24, 1945, aged 29, of tuberculosis of the spine.

Reuben Jordan Maxwell, Sulligant, Ala.; Washington University School of Medicine, St. Louis, 1939; interned at St. Louis City Hospital, where he served a residency; began active duty as a first lieutenant in the medical corps, Army of the United States, in August 1941; promoted to captain and major; died while aboard the steamship *Haskell* Oct. 10, 1945, aged 32, of poliomyelitis.

Howard Mitchell, Toronto, Ont., Canada; born in New York Nov. 19, 1917; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1941; interned at the Franklin Hospital in San Francisco; began active duty as a first lieutenant in the medical corps, Army of the United States, in August 1942; assigned to the medical detachment 376th Infantry, 94th Infantry Division at Fort Custer, Mich.; in October 1942 transferred with that division to Camp Phillips, Salina, Kan., where he served until July 1943, when he was assigned to duty with the 68th Medical Regiment at Camp Forrest, Tenn.; promoted to the grade of captain in November 1943 and assigned to duty with the 618th Clearing Company; died aboard a U. S. Army transport in the European area Dec. 12, 1943, aged 26, of acute lobar pneumonia.

Samuel Alfred Murphy, Wilkinsburg, Pa.; University of Illinois College of Medicine, Chicago, 1920; began active duty as a captain in the medical corps, Army of the United States, in April 1944; served with the Veterans Administration Facility in Pittsburgh; died in the Deshon General Hospital, Butler, Pa., June 18, 1945, aged 56, of perforation of the esophagus.

Robert Kazuo Ota, Milwaukee; Marquette University School of Medicine, Milwaukee, 1939; interned at St. Luke's Hospital and the Johnston Emergency Hospital; lieutenant, medical corps, Army of the United States; died in the Madigan General Hospital in Tacoma, Wash., Jan. 16, 1946, aged 35.

Nicholas Polites, Atlantic City, N. J.; Emory University School of Medicine, Atlanta, 1936; served an internship and residency at the James Walker Memorial Hospital in Wilmington, N. C.; interned at St. Joseph's Infirmary in Atlanta; began active duty as a first lieutenant in the medical reserve corps of the U. S. Army in 1941; promoted to captain in February 1942 and major in October 1943; killed in Germany Nov. 8, 1945, aged 38, in an airplane crash.

Morris Ruchelman, Brooklyn; Louisiana State University School of Medicine, New Orleans, 1942; interned at the Touro Infirmary in New Orleans; entered active duty in the medical corps, Army of the United States, as a first lieutenant in April 1943; promoted to captain; killed in an airplane accident in Sicily Nov. 9, 1945, aged 28.

John Hurst Wenger, Terre Hill, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1941; interned at the Philadelphia General Hospital in Philadelphia; captain, medical corps, Army of the United States; died in France June 16, 1945, aged 30.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Aug. 2, 1947.

The Outbreak of Infantile Paralysis

The outbreak of infantile paralysis, described in a previous letter, continues. New cases are announced daily both in London and throughout the country. The incidence of the disease is higher than at any time during the last thirty-five years, the period for which records have been kept. There are 112 confirmed or suspected cases in the London hospitals. As the peak period of the disease is usually in the autumn, it is thought that there may be worse to come. Owing to the outbreak, 150 London children who were to have been included in a party of 500 from industrial districts of England and Scotland going to Belgium on vacation next month have had their trip canceled. For the week ended July 26 the number of cases in Britain is expected to be not fewer than 300, compared with 177 in the week before and with the highest weekly figure of 85 in previous years. The cases are occurring in different parts of the country, and there is nothing to suggest spreading from one center. The disease is proving difficult to control because it is not always identifiable in cases of mild and indefinite illness and because it may be harbored by healthy carriers whom it is impossible to recognize. The holiday exchange of children between Britain and the European continent, which had been arranged by the World Friendship Association, has been stopped. It has been suggested that all bathing should be stopped, because of the danger of acquiring the virus.

Answering questions in the House of Commons, the minister of health stated that the present rate had never been exceeded in this country since the disease became notifiable. The best precautions were personal hygiene, avoidance of close congregation of young people and early medical advice if a young contact of a known case showed any mild or indefinite illness. One of the most discouraging features of the incidence of the disease was that it had reached its peak earlier in the year than usual. There was no evidence of the slightest connection with malnutrition. Notifications of the disease for the week ended July 26 in England and Wales numbered 302 compared with 177 in the previous week, and there is nothing to suggest that the peak has been reached; the figures suggest a further rise. Notifications reached double figures for the week ended July 26 in London (51) and in seven English counties. Although the cases are widely scattered, the incidence is by no means even. The mechanism of direct spread is still uncertain, but it has become increasingly evident that spread is usually from person to person following close contact with a case of abortive or paralytic disease during a relatively short period of infectivity, which begins a few days before any sign of illness. The latest figures published show 448 cases for the week ended August 2, an increase of 146 on the previous week and the highest for any week of the outbreak. Of these 53 occurred in London.

The British Medical Association and the National Health Service Act

For some time negotiations have been taking place between the government and the British Medical Association with regard to the National Health Service, which is now law. Concern is felt in the profession as to these negotiations because, as is usual, they have not been disclosed while in progress. At the annual representative meeting of the association, recently held in London, the chairman of the council, Dr. H. G. Dain, presented a report on the progress of the talks. The minister of health, Mr. Bevan, agreed to enter into discussions of a comprehensive character in which the possibility of fresh legislation was not ruled out. Subcommittees of the negotiating committee of the association were set up to deal with various sections of the act under such headings as specialists and consultants, hospital service, general practice, public health, superannuation, ophthalmic services and mental services. Discussions took place between these subcommittees and the officers of the ministry. These discussions were comprehensive, and no attempt was made to limit them or tie the subcommittees down to regulations only. They stuck to their principles and argued in favor of them as vigorously as they could. They did not make concessions or retreat from any position taken up. No fear need be entertained that the discussions involved acceptance of things of which the association would not approve. A detailed report on the subject will later be given to the representative body of the association. In order to ensure that the arguments used to the officers of the Ministry of Health may not reach the minister in a milder form, he will be offered a report in writing prepared by the subcommittees. Further, it is proposed to ask him to talk personally with some of the subcommittees—those representing consultants and specialists, general practitioners and public health.

A resolution was introduced at the meeting of the representative body asking the negotiating committee to make an early report of the progress and discussions with the minister, because of the uneasiness felt in the profession as to what was going on behind closed doors. After discussion, in which the chairman of the council of the association pointed out that there was no alteration of the position to report and would not be until the minister's reply was forthcoming, the resolution was put to the meeting and lost by a large majority.

International Congress of Physicians

Since the end of the war London has become almost the sole meeting place of international congresses. In September there will be a medical one, to be followed almost immediately by a surgical one.

An international conference of physicians is to be held at the Royal College of Physicians, London, on September 8, to continue daily at various institutions and hospitals in London until September 12. In addition to the scientific program there will be a social one, which will include a government luncheon, a banquet at the Guildhall and a reception at the College. Admission is confined to medical practitioners and is by invitation only. Application for admission must be made to the organizing secretary, Dr. G. B. Mitchell-Heggs, in care of Royal College of Physicians, Pall Mall East, London, S. W.

Section of Cardiology: Surgery of Congenital Heart Disease, Pulmonary Heart Failure (with Section of Disorders of the Chest). Use of the Phonocardiogram in Clinical Cardiology. Repetitive Paroxysmal Tachycardia.

Section on Disorders of the Chest: Transient Pulmonary Infiltrations. Pulmonary Heart Failure. Sarcoidosis (with Section of Dermatology). BCG Vaccination.

Section of Dermatology: Vitamin D in the Treatment of Cutaneous Tuberculosis Sarcoidosis.

Section of Neurology: Malnutrition of the Nervous System. The Role of the Pyramidal System in Movement. Spinal Fluid. and Cerebral Fluid—A Comparison. The Functions and Connections of the Frontal Lobes (with Section of Psychiatry).

Section of Pediatrics: Surgery of Congenital Heart Disease. Hemolytic Anemia. BCG Vaccination (with Sections of Social Medicine and Disorders of the Chest).

Section of Psychiatry: Genetics in Relation to Mental Deficiency. Psychodynamics of Depression. Social Surveys (with Section on Social Medicine). The Functions of the Frontal Lobes (with Section of Neurology).

Section of Social Medicine: Care of the Aged and Infirm. Social Medicine in the Curriculum. Social Surveys. BCG Vaccination.

Section of General Medicine: Penicillin. Infective Hepatitis. Pain.

International Congress of Surgeons

The twelfth congress of the International Society of Surgery will be held in London from September 14 to 20. The secretary is Mr. H. W. S. Wright, 9 Weymouth Street, London, W. 1. Applications for membership in the society may be made at any time.

BELGIUM

(From Our Regular Correspondent)

Aug. 1, 1947.

Treatment of Persistent Ductus Arteriosus and Coarctation of Aorta

At the society of surgery Dr. G. Coryn reported observations made during a stay in Stockholm with regard to the technic used by Dr. Clarence Crafoord in the surgical treatment of persistent ductus arteriosus and coarctation of the aorta.

In cases of persistent ductus arteriosus, Crafoord found retardation of statural development in only 10 per cent of his patients. He thinks that, in view of the poor prognosis, the diagnosis of the persistence of the ductus constitutes an absolute indication for operation. Seventy patients without complications have been operated on with 1 death. Of 7 patients with malignant endocarditis, 5 were successfully operated on and 2 died.

In describing the technic, Crafoord rejects the anterior approach. Contrary to Sellors, Crafoord thinks that the caliber and length of the ductus arteriosus varies in different subjects and that they decide the mode of treatment. If the duct is long and wide, the double ligature is employed and several drops of a 60 per cent dextrose solution are injected between the ligatures. If the duct is very short and very large, it is necessary to interrupt the flow of the blood in the aorta between two clamps, partially in the pulmonary artery, sectioning the duct and suturing the two gaps.

Crafoord thinks that coarctation of the aorta is related to the involution of the ductus arteriosus. The diagnosis is based on the chief sign of disparity between the arterial pressure of the upper and lower extremities. The prognosis being unfavorable, indication for surgery is absolute. It is, however, feasible only if the narrowing is located upstream to the subclavian artery. End to end suture must be done after *resection* of the narrowed constricted portion. Fifteen patients have been operated on with a single death.

Quinine in the Belgian Congo

Bruxelles-médical recalls that it was one of the very first to concern itself with the production of quinine in the Belgian colonies in Africa. Since then this question has progressed rapidly. The invasion of the Netherlands Indies by the Japanese gave to the Congo quinine a place of first importance. The Belgian Congo was in effect the only African colony where the cultivation of cinchona was intensified to the point of undertaking to manufacture of quinine right there. The work was consigned to a governmental directorate controlling not only the manufacture and the sale but also the purchase of the cinchona bark from the planters. At the return to more normal conditions the present organization will be completely modified. Negotiations to this effect are going on between the minister of colonies, the planters and interested organizations. Agreements in principle have been reached. The quinine office and the directorate of the Congo will be replaced by a cooperative joining all those interested with the participation and under the control of the government. The manufacture of quinine will be continued in the Congo, where the cultivation of cinchona will be intensified to a maximum.

Children and the War

Lust presents a study in *Scalpel* on the influence of the food supply during the German occupation on the birth rate, the infant morbidity and mortality and maternal lactation. He interprets the statistics on the birth rate and infant mortality during the German occupation on the basis of an investigation in forty infant consultation centers in urban and rural localities of Walloon and Flanders. The number of births decreased during the occupation from 130,000 in 1939 to 100,000 in 1941; the birth rate then decreased from 170,000 in 1913 to 85,000 in 1917.

The infant mortality rate, which during the years preceding the invasion remained stationary at about 8 per cent, increased at least at the beginning of the occupation, reaching above 9 per cent. This rather high infant mortality cannot be attributed to the frequency of congenital debility of the newborn, to the poor nutrition of the nurslings, which remained satisfactory throughout the entire war, to acute infectious diseases, which are not abnormally frequent, or to tuberculosis.

Too many of the mothers do not make the necessary effort to nurse their newborn. The percentage of infants being entirely or partly maintained by breast feeding at the time of their admission at nursling consultation centers at the age of 6 weeks was only 35 per cent in 1939. This percentage exceeded 50 per cent at the onset of the occupation; since then this percentage has tended to diminish every year.

Anilinism

Merevelde reported in the *Revue médicale de Louvain* a number of cases of aniline intoxication among workers and other persons. Among the latter there was a child aged 9 months who was found in deep cyanosis, with attacks of vomiting. The child had been in a kitchen where the mother had dried a brown leather garment which had been dyed with aniline dye. Merevelde discusses the chemical properties of aniline, and symptoms of acute and chronic intoxication. He cites personal investigations to which he exposed himself with the aim of clarifying the pathogenesis of the intoxication (variations in the hemogram, the iron content of the plasma, the rapidity of the sedimentation speed and the changes in vitamin C). In cases in which acute and severe cyanosis or coma exists, the chief aim of treatment should always be the prompt employment of drugs which augment the respiratory capacity, such as nikethamide. In extremely severe cases venesection is indicated as well as transfusion and injection of methylene blue. The further treatment must aim to counteract the anemia.

Professor A. P. Dustin

The Royal Academy of Medicine paid homage to Professor A. P. Dustin. The funeral eulogy was delivered by Professor Dalcq, who recalled how, as prorector of the university and as president of the faculty of medicine, the eminent scientist was arrested in the tragic hours of the Nazi occupation and incarcerated for three months at the citadel of Huy, where each evening the quarters of the hostages were transformed into a seminary of studies, of which Dustin was the most enthusiastic supporter. He wore himself out like a true patriot and was proud of the salutary effect which his attitude had on the oppressed population. His sudden death after an afternoon of microscopic studies was a magnificent example of civic and scientific courage. Corresponding member of the academy since 1921 and titular since 1931, A. P. Dustin, son of Pierre Dustin, communal administrator to whom Brussels chiefly owes the creation of its port, and of an intelligent and cultured mother, was at the same time an eminent neurologist, histologist and embryologist. After research work in the laboratory of Professor Prenant and in that of Roscoff, he became professor at the age of 25 years. During World War I he distinguished himself by his work in neurosurgery. For twenty years he occupied the chair of neuropsychology at the War College. One is astounded at the extent and importance of his studies on cancerology, the karyoclastic poisons, the technic of biopsies, histophysiology, his numerous conferences in Belgium and in foreign countries, the great number of students that surrounded him in his laboratory, the variety of his literary and artistic culture, his administrative competence and his rare talent in lecturing and persuasion.

Correspondence

MEDICAL MISSION TO AUSTRIA

To the Editor:—It occurred to the director of the Medical Mission to Austria that a few comments on our experience of the past five or six weeks might be of interest to readers of The Journal. The mission has been operated by the Unitarian Service Committee under the auspices of the World Health Organization of the United Nations. It represents the first such mission to be sent by the World Health Organization into a foreign country for the purpose of exchanging ideas with university groups. Its eight physicians from the United States and two from Switzerland have held discussions on medical progress in physiology, pharmacology, cancer research and genetics, internal medicine, infectious diseases, neuropsychiatry, general surgery, neurosurgery and anesthesia. At the invitation of the Austrian minister of public welfare and of the various faculties, the group has been received at Vienna, Graz and Innsbruck. Formal receptions have been followed by a series of prepared lectures and by informal discussions with individual groups or with individual faculty members. The facilities of the state and of the various Allied commands have been put at our disposal; and important help has been freely given by the United States legation in Vienna and by Colonel Cottrell, the World Health Organization representative in Austria.

Despite differences in language and in academic traditions, we have had few real difficulties once the nature of the mission became understood. University doors have been opened wide, and in most instances there has been free and informal discussion. The free interchange of ideas has been stressed and accomplished. Because of the isolation of the Austrian clinics from the outside world during the war, we have been able to present new ideas and new procedures which, in the main, have been welcome. Advances in surgical procedure and anesthesia have been demonstrated and have created wide interest. Newer physiologic concepts and recent clinical developments similarly have been received usually with enthusiasm.

As material difficulties exist, owing to lack of equipment, drugs and food, many therapeutic measures have met with somewhat qualified enthusiasm. The practical realities of an impoverished and occupied country preclude easy acceptance of scientific measures that people in the United States take for granted. Nevertheless with few individual exceptions an interest has been encountered throughout our stay. All of us have made new professional friendships that may presage a future mutual interchange of ideas of real value.

The immediate and practical result of a mission such as this is less clear. In a country where fear and uncertainty are universal, where nutrition is marginal and where the necessities of life are difficult to obtain, stimulating scientific thinking can be accomplished only by intense personal effort and sacrifice. Austria and Austrian physicians are acutely aware of the immediate problems of political and physical survival that are almost insuperable. It is not surprising, therefore, that at times we have encountered apathy and discouragement and a concern for the immediate present.

In the universities the remaining professors are overworked. The student bodies are so large that they are unwieldy and teaching for the most part must be purely didactic. Supplies of the simplest nature are so limited that only the simplest procedures can be carried out in most instances. Deficiencies in drugs are everywhere apparent, and makeshift therapy which is frequently ineffective may represent the only possible approach to medical problems. Special diets with adequate caloric and protein content are practically unobtainable. Medical literature from 1938 to the present is notable for its absence.

The immediate situation is one of great difficulty, and no one is more aware of this than the majority of the faculty members. The most serious lack in the immediate future is the large number of only partially trained younger men in all departments of the medical schools. Losses by war, political and racial purges and displacements have left a large number of important subordinate positions and some major posts that can be filled satisfactorily only after the lapse of years. In spite of difficulties, many of the abler men are carrying a tremendous overload of teaching and practice with a courage and devotion to academic traditions that is inspiring.

The experience of the mission as far as its members are concerned has been of great value. We have proved, we think, that a sympathetic approach by experienced, trained men can meet with a friendly reception in spite of traditional difference of thought and in spite of material and psychologic differences inherent in a postwar situation. The practical contributions of the mission are difficult to evaluate at close range but are of real magnitude. To ourselves and to our Austrian hosts this mission has effected an exchange of intangible values that may be of great importance.

Chester M. Jones, M.D., Innsbruck, Austria.

DERMATITIS DUE TO QUINACRINE HYDROCHLORIDE (ATABRINE)

To the Editor:—The paper by T. W. Nisbet in The Journal May 31 might be open to criticism on one small point on page 447, where one finds "It has been stated that this symptom complex did not occur in the Mediterranean area though certain units were in malaria-infested districts and the troops were taking quinacrine hydrochloride. However, this is not the case, and several examples of the lichenoid type of eruption occurring in British soldiers have been presented before the Section on Dermatology of the Royal Society of Medicine, although the causative factor of quinacrine hydrochloride was not recognized."

In September and October 1943 in Algeria a series of both the lichenoid and eczematous types of drug eruption due to quinacrine hydrochloride were observed and discussed by Major L. M. Nelson, M. C., A. U. S., Major H. C. Hair, M. B. E., R. C. A. M. C., and myself. At this time we considered the possibility of this strange rash being either a multiple hypovitaminosis or an eruption due to mepacrine, but the patients could not be kept under observation, as the three of us were transferred to Italy.

We saw a considerable number of men suffering from similar manifestations in Italy and discussed its etiology with Major R. N. Buchanan, M. C., A. U. S. In 1944 Major Hair and I reported on the dermatosis to the War Office in London, but publication was withheld until the end of 1946. This report, without any alterations, was published in the *British Journal of Dermatology and Syphilis* (**58**:263, 1946). Major Nelson similarly forwarded a report which was published in the *Archives of Dermatology and Syphilology* (**55**:13 [Jan.] 1947).

As Dr. Nisbet's paper was read in July 1946 before the Section on Dermatology and Syphilology of the American Medical Association, he could not possibly have been aware of the article by Hair and myself, which was not published until November/December of that year. It seems only right to explain that dermatologists in the Mediterranean area were not mentally asleep at their posts and had recognized these cases about the same time (if not before) as the dermatologists in the Pacific.

Assistant Physician, Skin Department, Royal Infirmary.

Medical Motion Pictures

FILM REVIEWS

The Technic of Atraumatic Convulsive Therapy. Prepared in 1947 by Matthew Brody, M.D., Department of Neurology, Jewish Hospital and the Division of Neuropsychiatry, Brooklyn Hospital, Brooklyn. 16 mm., color, silent, 400 feet (one reel). Showing time sixteen minutes. Procurable on loan from the Author: 41 Eastern Parkway, Brooklyn 17.

This film begins by illustrating the induction of an electroshock convulsion in a woman aged 52 diagnosed as suffering from an "involutional melancholia." The technic first shown is purported to be "orthodox," yet the patient is treated fully clothed and apparently corseted; also she is made to lie on a soft couch, and her convulsive movements are restrained only by the physician and a nurse. Subsequent scenes illustrate what are represented as improvements in this technic; namely, 200 to 300 mg. of sodium pentothal is administered intravenously to diminish fear and resistance, and this is followed by the immediate injection of 0.5 to 0.75 unit of intocostrin (an active ingredient of curare) to diminish the intensity of the muscular contractions. Three or four minutes later, when the patient can no longer raise her head, the current is passed through the cranial electrodes and breathing during the ensuing convulsion is facilitated by the insertion of a rubber airway. These technics are shown in the treatment of a young man labeled "Dementia Precox, Catatonic Type," a woman aged 65 with an "Agitated Depression" and [sic] arteriosclerosis with aortic dilatation, and finally in a girl aged 17 years with hebephrenia and active pulmonary tuberculosis.

The scenes are well photographed and clearly subtitled, although there is unnecessary preoccupation with details such as the filling of syringes and the mode of venipuncture. The great defects in this film, however, lie not in its subject matter but in its basic orientation and intent. The title of the film is misleading, since evidence is accumulating that (*a*) the passage of a 60 cycle alternating current through the brain for 0.3 to 0.5 second is inevitably traumatic to cerebral tissues, and (*b*) such treatment has little or no lasting curative value in schizophrenia; indeed, electroshock is definitely contraindicated in many cases so diagnosed. The film is very remiss in neglecting to emphasize the dangers and complications inherent in the intravenous administration of powerful drugs such as pentothal and curare, and the great care that must be used in administering electroshock to patients with cardiovascular, pulmonic and other systemic diseases. On the contrary, the film as a whole and the concluding subtitles in particular convey the impression that, if the modifications of technic are employed as illustrated, electroshock therapy can be given to almost any one in an office anteroom, with little or no danger of serious complications. Neuropsychiatrists experienced in the field know better; but if the film is addressed to the general practitioner it conveys dangerous misinformation. For this reason the film cannot be recommended for general distribution.

Ether for Anesthesia. Produced in 1946 by Audio Productions, Inc., New York. 16 mm., black and white, sound, 750 feet (one reel). Showing time twenty-one minutes. Procurable from Mallinckrodt Chemical Works, St. Louis 7.

This excellent motion picture presents in an interesting fashion the detailed history of the chemical production of ether and a brief view of the contrast between its present day application in anesthesiology and its use in Morton's crude inhaler a century ago. A considerable part of the film is devoted to the evolution of methods of distillation from the times of Aristotle and Pliny, through the first synthesis of ether in 1540 by Valerius Gordus to the very modern chemical plant with its intricate methods of production, purification and safe packaging of ether. The photography and general treatment are excellent.

This film should be of value to chemists and pharmacists and be useful in a teaching program in those fields. It also has application in the presentation of the history of medicine. It is a useful film in the training of anesthesiologists.

The Use of Sulfathalidine in Chronic Ulcerative Colitis. Prepared by Michael H. Streicher, M.D., University of Illinois College of Medicine. 16 mm., color, sound, 650 feet (one reel). Showing time eighteen minutes. Produced in 1946 by Audio Productions, Inc., New York. Procurable on loan from Sharpe and Dohme, Inc., Philadelphia.

The film depicts the story of one form of chronic ulcerative colitis rather well. It fails to differentiate between this and the other forms of chronic ulcerative colitis, and in the pathologic description the ulcers which have always been considered to be of the secondary type are described as being the primary ulcers of this condition. The material is well prepared, and the emphasis on laboratory control is well taken.

The film has good teaching value, but there may be too much emphasis on some things. The Paulson and other personal references might well be omitted. More emphasis could be laid on the fact that this is *only one form* of therapy employed as a part of a large armamentarium used in the treatment of this disease.

The film could readily be used to give an audience a general conception of ulcerative colitis. It would be more suitable for hospital personnel such as nurses, technicians and attendants than for presentation before medical students and medical societies. This statement is made because of the stress laid on the appearance of patients and the rather general description of this disease rather than the more specific detailed description. The color photography is excellent.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

BOARDS OF MEDICAL EXAMINERS
BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of the boards of medical examiners and boards of examiners in the basic sciences were published in The Journal Sept. 6, page 53.

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Parts I and II.* Various centers, Sept. 15-17. *Part III.* Durham, N. C., Oct. 21-23. Exec. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia 2.

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: Part II. *Oral.* Cleveland, Oct. 5-11. Sec., Dr. P. M. Wood, 745 Fifth Ave., New York 22.

American Board of Dermatology and Syphilology: *Part II. Written.* Various centers, Sept. 15. Sec., Dr. G. M. Lewis, 66 E. 66th St., New York 21.

American Board of Internal Medicine: *Oral.* Chicago, Oct. 8-10. Asst. Sec., Dr. W. A. Werrell, 1 West Main St., Madison 3.

American Board of Neurological Surgery: *Oral.* Chicago, May or June. Final date for filing application is Feb. 1. Sec., Dr. W. J. German, 310 Cedar St., New Haven, Conn.

American Board of Obstetrics and Gynecology: *Part I. Written.* Various Centers, Feb. 6. Final date for filing application is Nov. 1. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh 6.

American Board of Ophthalmology: Chicago, Oct. 6-12. Sec., Dr. S. Judd Beach, 704 Congress St., Portland, Me.

American Board of Orthopaedic Surgery: Part II. Chicago, Jan. 22-23. Final date for filing applications is Sept. 15. Sec., Dr. F. M. McKeever, 1136 W. Sixth St., Los Angeles 14.

American Board of Otolaryngology: Chicago, Oct. 7-11. Sec., Dr. D. M. Lierle, University Hospitals, Iowa City.

American Board of Pathology: Chicago, Oct. 24-25. Final date for filing application is Sept. 15. Sec., Dr. Robert A. Moore, Euclid Ave. and Kingshighway, St. Louis 10.

American Board of Pediatrics: Dallas, Dec. 5-7. Philadelphia, Jan. 9-11. Sec., Dr. Lee F. Hill, 718 Royal Union Bldg., Des Moines 9.

American Board of Plastic Surgery: Examinations are given in April and November of each year in the home town of applicants. Sec., Dr. Louis T. Byars, 508 N. Grand Blvd., St. Louis.

American Board of Psychiatry and Neurology: *Oral.* New York, December. Final date for filing application is Sept. 15. Sec., Dr. Francis J. Braceland, 102-110 Second Ave., S. W., Rochester, Minn.

American Board of Surgery: *Written.* Various Centers, March. Final date for filing application is Dec. 1. Sec., Dr. J. S. Rodman, 225 S. 15th St., Philadelphia 2.

American Board of Urology: Chicago, February. Final date for filing application is Nov. 1. Sec., Dr. Harry Culver, 1409 Willow St., Minneapolis 4.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Elements of Damage Which May Be Considered.—The plaintiff sued for damages alleged to have resulted from the failure of the defendant physician to attend her during a miscarriage. From an order granting the defendant's motion for a nonsuit, the plaintiff appealed to the Supreme Court of New Hampshire.

The defendant was engaged to furnish the plaintiff necessary care and treatment during her pregnancy. Three months prior to the time the child was expected the plaintiff commenced to flow. On advice of the defendant physician the plaintiff remained in bed, and in a few days the flowing had ceased and the plaintiff felt well again. A few days later, however, at about 4 o'clock in the morning, the plaintiff awoke in pain. Without knowing their nature she was having labor pains, and the child was born between 12 and 1 o'clock. According to the plaintiff's evidence, her husband telephoned the defendant physician about 9 o'clock in the morning to come and not until a fourth call informing him that a miscarriage had taken or was taking place on the toilet did the doctor arrive.

In discussing the question of damages, the court said that damages cannot be given for the mere fact of the miscarriage. The evidence indicated that it would have occurred anyway. Nor can they be given for the physical and mental suffering that the wife would have endured under the usual circumstances that would have accompanied the miscarriage. The plaintiff is entitled to recover, however, for any and all pains of childbirth and of the following bodily conditions that were not prevented or eased because of the negligent failure of the physician to attend or prescribe. "There may be a recovery for the increased physical and mental suffering the wife endures on account of the nonattendance of a physician. . . ." I Sutherland Damages 4th Edition, 352. If the defendant had been in attendance, the child would have been born in bed, narcotics or other medicines could have been prescribed to relieve the pains of the mother and other medical care of her taken. The mere assuring presence of the physician at such a time would have been a comfort to which the plaintiff might be found entitled. The defendant argues that the wife cannot have damages for grief over the manner in which the child was born or for anticipation of it, which anticipation did not exist. This is true, concluded the court, but she may recover for injured feelings attending the happening of the birth in the way that it did. Present mental suffering due to the immediate realization of what is occurring or has occurred that is not grief in retrospect is compensable.

The judgment in favor of the defendant physician was reversed and a new trial ordered.—*Mehigan v. Sheehan, 51 A. (2d) 632 (New Hampshire, 1947).*

Liability of Hospital for Injuries to Unattended Patient.—The plaintiff sued the defendant hospital for damages for injuries alleged to be due to the defendant's negligence in failing to provide him with the services of nurses, orderlies or other attendants commensurate with his known physical condition and needs. From a judgment in favor of the plaintiff the defendant appealed to the Supreme Court of Appeals of Virginia.

The plaintiff entered the defendant hospital as a pay patient for the purpose of having a cataract removed from his right eye. The day following his entry, the cataract was successfully removed and he was returned to his room in the hospital. The room to which the plaintiff had been assigned had no separate bath or toilet, and he had been instructed both by his physician and by the hospital attendants that when he desired to answer a call of nature he should ring for a nurse, who in turn would dispatch to him an orderly who would attend to his needs through the use of a bed pan in his room. He was cautioned that he should not attempt, without the assistance of an orderly, to get out of bed and attend to his needs in this respect. A few nights later, between 9 and 10 o'clock, the plaintiff felt the urge of an impending bowel movement. In accordance with the instructions previously given him, he signaled for a nurse by pressing the nearby electric button which illuminated a red signal light above the door. After waiting for a period of from ten to fifteen minutes, the plaintiff turned off the signal light and flashed it on again. No one came, however. In the meantime his discomfort and pain had become acute. To use his own words, "I felt that I would have an accident if I didn't do something." He therefore arose from the bed and procured the bed pan, which was on a chair in his room. The door leading from his room into the corridor was opened and people were passing back and forth; consequently he felt some embarrassment in undertaking to use the bedpan in the room. He walked toward what he thought was a washroom in the corner of his bedroom and opened the door, hoping that he might retire there and relieve himself, but found that it was too small for the intended use. He then closed the door of the washroom and turned away and, as he did so, his foot slipped and he fell, fracturing his hip.

The hospital contended that the evidence fell short of the legal requirements in two respects: (1) It failed to show that the defendant, or any of its employees, was guilty of negligence, and (2) it shows that the proximate cause of the plaintiff's injury was his own voluntary act in undertaking to attend to his own needs when he knew, or ought to have known, that he was in no condition to do so.

The degree of care exacted of a private hospital, conducted for profit, to their patients "is such reasonable care and attention for their safety as their mental and physical condition, if known, may require, and should be in proportion to the physical or mental ailments of the patient, rendering him unable to look after his own safety."

The troublesome question presented to us, continued the court, and that most seriously pressed, is whether the negligence of the hospital in failing to heed the plaintiff's call and in failing to attend to his needs was the remote cause, and his own act in getting out of bed and attempting to administer to himself was the direct and proximate cause of his fall and consequent injuries. An intervening cause, said the court, does not operate to exempt a defendant from liability if that cause is put into operation by the defendant's wrongful act or omission. Tested by this principle, the court continued, we think the jury was fully warranted in finding that the plaintiff's action in attempting to attend to his needs under the circumstances was not a superseding cause of his injury but was merely a circumstance in a continuous sequence of events—that is, a connecting link between the negligence of the hospital and his injury. The intervening act of the plaintiff was put into operation by the hospital's wrongful act or omission. His act was "a normal response to the stimulus" of the situation created by the hospital's negligent conduct. When the hospital attendants failed to respond to his call and administer to his needs, it was both natural and probable that he would undertake to relieve himself of the painful and embarrassing situation in which he had been placed by the primary act or omission of the hospital. Moreover, the hospital attendants knew, or should have known, that as a consequence of their neglect of his needs the plaintiff probably would undertake to get out of bed and wait on himself. Both the nurse and an orderly said that he had done so on other occasions. An intervening cause will not be deemed to have broken the causal connection if the intervening cause was foreseen or reasonably might have been foreseen by the wrongdoer. The plaintiff's conduct was involuntary. He was driven by pain and natural impulse to get relief by waiting on himself. His situation was akin to that in which a person put in peril by the negligent act of another, and in the instinctive effort to escape therefrom, suffers injury. In such a situation the negligent act is deemed the proximate cause of the injury. Accordingly the court affirmed the judgment of the trial court in favor of the plaintiff.—*Jefferson Hospital, Inc. v. Van Leer, 41 S. E. (2d) 441 (Va., 1947).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them

Titles marked with an asterisk (*) are abstracted below.

American J. Digestive Diseases, Fort Wayne, Ind.

14:153-188 (May) 1947

The Obese Patient: Statistical Study and Analysis of Symptoms, Diagnosis and Metabolic Abnormalities. Sex Differences—Treatment. H. M. Ray.—p. 153.
Report of Case of Spontaneous Cholecystoduodenostomy. G. J. Culver and J. R. Kline.—p. 162.
*Diabetes Mellitus Complicated by Addison's Disease: Case Report, with a Review of the Literature. J. S. Devitt and J. C. Murphy.—p. 164.
New Hemostatic Agents in Proctology. A. J. Cantor.—p. 166.
*Azotemia in Gastrointestinal Hemorrhage. A. Schrumpf.—p. 169.
Creed for the Treatment of Diabetes. G. F. Anderson.—p. 170.

Diabetes Mellitus Complicated by Addison's Disease.—The physiologic antagonism between the secretions of the adrenal cortex and the islands of Langerhans, according to Devitt and Murphy is well known. It is emphasized by the almost universal hypersensitiveness to insulin observed in diabetic persons with Addison's disease It is paradoxical that diabetes should develop at all in the presence of adrenal cortex insufficiency. A survey of literature confirms that diabetes is the antecedent disease in all except 3 instances of both endocrine disturbances in the same patients. The normal antagonism between the adrenal cortex and the islands of Langerhans was well demonstrated in a woman aged 28 by the occurrence of reciprocal exacerbations of one disease associated with remissions of the other. The authors emphasize that sensitivity to insulin is less pronounced when desoxycorticosterone acetate is employed in the treatment of Addison's disease, and under the same circumstances the diabetes may be more severe.

Azotemia in Gastrointestinal Hemorrhage.—Schrumpf concludes that azotemia after massive hemorrhage in the upper gastrointestinal tract is not caused by one single factor. The chief factor is of dietetic origin, as the diet used is insufficient in protein and energy requirements. This again increases protein catabolism and waste of tissue. A second factor is the absorption of blood, which to a certain but moderate degree can play a part in the development of the initial azotemia. All other factors seem to be of little or no importance.

Immunity to Yellow Fever Five Years After Vaccination.—Anderson and Gast-Galvis report the results of studies recently made with 17 D yellow fever virus in a selected group of vaccinated persons in four Colombian towns. Their aim was to determine what changes had occurred in the immune status since vaccination and whether revaccination appeared advisable. Serums were obtained approximately five years after vaccination and revealed a high proportion of persons with neutralizing antibodies in all age groups. The percentage is comparable with that reported in studies of serums drawn a few months after vaccination. It is concluded, therefore, that neither children nor adults require revaccination five years after vaccination.

Penicillin in Syphilis of Central Nervous System.—Heyman utilized a dosage ranging from 1.2 to 6 million units of penicillin in the treatment of 141 patients, 83 men and 58 women, with syphilis of the central nervous system. The patients were followed for six to nineteen months. It is believed that dosages less than 4,000,000 units will prove to be unsatisfactory. The total dosage of 4,000,000 units may be used in doses of 50,000 units every three hours for eighty injections in ten days. Preliminary observations indicate that this dosage will probably produce an arrest of the neurosyphilitic process in 85 per cent of the cases. Pronounced subjective improvement was frequently noted. Patients with early neurosyphilis obtained a better response to penicillin than late cases. No correlation was observed between the changes in the blood serologic tests and the response of spinal fluid following penicillin. The cell count of the spinal fluid was found to be a sensitive index of treatment failure. Thirteen of the 141 patients were found to have evidence of spinal fluid relapse following treatment. Approximately half of the patients who obtained normal or satisfactory spinal fluid findings had had adequate chemotherapy previously, indicating that penicillin has a far greater effect than routine chemotherapy on syphilis of the central nervous system. Penicillin is recommended for the treatment of early neurosyphilis and late asymptomatic neurosyphilis provided adequate facilities are available for follow-up examinations of the spinal fluid. In late symptomatic neurosyphilis penicillin does not replace fever therapy as the treatment of choice.

Streptomycin in Gram-Negative Bacillus Infections of Central Nervous System.—Paine and his co-workers treated 1 boy aged 14 and a 16 day old infant with meningitis due to Pseudomonas aeruginosa, 1 infant aged 4 months with meningitis due to Bacillus proteus morgani, and 2 infants aged 8 and 11 months respectively with meningitis due to Hemophilus influenzae type b by administering streptomycin. The 14 year old boy received a total of 28 Gm. of the drug intramuscularly and 0.45 Gm. intrathecally. The 4 infants received from 4.4 to 11.6 Gm. by the intramuscular route and from 0.225 to 0.75 Gm. by the intrathecal or the intraventricular route. The transient untoward effects of local use of streptomycin in 3 of the patients would indicate that the intraventricular and intrathecal routes should be used with caution. A prompt clinical and bacteriologic response occurred in 2 patients in whom penicillin and sulfonamide drugs proved ineffective, and in 1 patient in whom no other medications were used. A gradual response to streptomycin occurred in 1 patient in whom penicillin therapy was ineffective. In 1 of the patients with meningitis due to Hemophilus influenzae the institution of streptomycin may have affected a resolution of the disease process. Recovery occurred in all 5 cases. Streptomycin would seem to be the drug of choice in the treatment of meningitis due to these gram-negative bacilli.

Synthetic Lactobacillus Casei Factor in Pernicious Anemia.—Seven patients with pernicious anemia—4 women between the ages of 59 and 76 and 3 men between 64 and 70—were treated by Kurnick with synthetic Lactobacillus casei factor in doses of from 2.5 to 30 mg. daily by mouth. All patients gave a complete hematologic response, including reticulocyte count, red cell count, white cell count and platelet count, and correction of the megaloblastic dysplasia of the bone marrow. Reticulocytosis began between the fourth and seventh days and reached a peak two to four days later. Subjective improvement, most strikingly evidenced by greatly improved appetite, occurred usually on the third or fourth day of treatment. Glossitis and other gastrointestinal symptoms subsided within one week, and regeneration of papillae became apparent at this time. The minimal oral therapeutic dose for maximal response is 2.5 mg. or less daily. Combined sclerosis of the spinal cord is somewhat improved by folic acid therapy. The results are similar to those with liver. It is suggested that the Lactobacillus casei factor is either the anti-pernicious anemia factor or is utilized in its synthesis. Other compounds in liver with similar structures but without activity for L. casei may also be utilized by the human organism.

Improved Grafting Technic for Burns of Extremity.—Macomber and Patton present a grafting procedure which is especially advantageous in large single plaque burns of the extremities. It affords as advantages an ideal recipient site, the absence of infected, scar forming granulations beneath the grafts, minimal postoperative dressings, a shorter healing period and a softer, more pliable and durable graft.

Graft Fixation Beneath Tubed Pedicle Graft.—Sanders and Lynn call attention to the difficulties of applying adequate pressure dressings to split skin grafts on the donor areas beneath tubed pedicle flaps. They describe a satisfactory and efficient pressure dressing of the stent type which has resulted in complete takes of grafts beneath tubed pedicle flaps in 8 consecutive cases. This type of dressing has three advantages: 1. It provides firm fixation, immobilization and sufficient pressure on the graft. 2. It ensures protection and immobilization of the tube. 3. Cutting of the superficial gauze dressing makes the tube easily accessible for frequent inspection without disturbing the stent dressing on the graft. The stent dressing is left undisturbed for six or seven days, at the end of which time the sutures holding the stent in place are cut and likewise the sutures in the graft itself are cut and removed. It is important to leave the end-on mattress sutures in place for an additional four or five days. If this is not done, the area of the donor site will reexpand, pulling away from the edges of the graft, leaving a circumferential raw area between the graft and the skin edge.

Electroencephalographic and Histologic Changes Following Application of Graded Force.—Zimmerman and Putnam introduce a new method for the study of cortical cell change in connection with electroencephalographic deviations. The experiments were made on cats, and traumatizing activity was recorded in terms of voltage (intensity of force) and the duration of the force applied. The experiments were designed to investigate the possible relationship between the electroencephalographic patterns and the histopathologic changes occurring simultaneously after the application of graded force to the cortex. It was found that electroencephalographic changes vary with the amount of cortical cell damage within a certain critical range. Below this critical range cortical cell change occurs without corresponding electroencephalographic deviations. Within the critical range the amount of electrical and cortical cell change is directly proportional to the amount of force applied to the cortex. Localized cortical cell damage produces localized electroencephalographic changes. Histologic changes assume a definite pattern of stratification, according to the amount of force applied to the cortex. Electroencephalographic changes vary with the amount of force applied to the cortex. Reduction in amplitude is directly proportional to the amount of force delivered. The appearance of slow waves is inversely proportional to the amount of force applied to the cortex. Unilateral convulsive electrical patterns were produced by the mechanical application of force to the cortex.

Histopathologic Changes in Poliomyelitis.—Scheinker thinks that these histopathologic aspects of human poliomyeliti remain controversial: (1) the localization of the disease an its distribution; (2) the primary type of the essential lesions (3) the correlation of the neuronal damage and the meso dermalglia alterations, and (4) the role played by the microglia He reviews some of the conflicting views and presents detaile studies on 6 cases of acute anterior poliomyelitis. Wherea until recently acute anterior poliomyelitis was regarded b clinicians and pathologists as a disease of the anterior horn of the spinal cord, the present study demonstrates that n part of the central nervous system entirely escapes damage The medulla, pons, midbrain, hypothalamus and cerebellum were involved to a great extent in every case. There was no direct correlation between the degenerative neuronal changes and the inflammatory reaction, so that they may be independent phenomena. Both diffuse and focal proliferations of microglia cells were noted as predominant tissue reactions in all cases. The pronounced concentration of the inflammatory and degenerative tissue reactions in the region of the vagal nuclei provides additional suggestive evidence of the possible spread of the virus from the intestine into the central nervous system by way of the afferent and efferent pathways of the vagus nerve.

Meningeal Gliomatosis.—Polmeteer and Kernohan say that in a survey of the glioma group of neoplasms observed at the Mayo Clinic from 1922 to 1942 generalized meningeal gliomatosis was found in 42 instances. The medulloblastoma was responsible for generalized metastases in 47.6 per cent of the cases. Glioblastoma multiforme represented 14.3 per cent of the series, ependymoma and ependymoblastoma 11.9 per cent, oligodendroglioma and oligodendroblastoma 11.9 per cent, astrocytoma 7.1 per cent, retinoblastoma 4.8 per cent and pinealoma 2.4 per cent. Although several instances of extracranial metastasis from gliomas have been reported, in this series the metastatic implants were limited to the central nervous system. The metastatic growths were more or less confined to the subarachnoid space. The pia mater and the subarachnoid space, which are extremely vascular, furnish a suitable environment for the nutrition and the survival of the cells of the tumor. The extension of the cells is limited peripherally by the fibrous, inelastic and avascular dura mater and arachnoid membrane and centrally by the compact structures of the brain and spinal cord. In the majority of cases the cells of the metastatic tissue were easier to identify than those of the primary tumors, probably because they grew on a free surface and the morphologic characteristics of these cells were unaltered by the pressure of the adjacent cerebral and spinal structures. Contrary to the general belief that only the more malignant varieties of glioma produce generalized meningeal gliomatosis, the authors found that this process may result from almost any variety of glioma.

Cancer Problem. D. A. Wood and M. B. Shimkin.—p. 364.

Subacute Generalized Neuromuscular Exhaustion.—The syndrome presented by Nielsen develops subacutely after severe overexertion which itself occurs during a period of euphoria. The patient suddenly becomes aware of utter exhaustion approaching paralysis of the entire body but most intensely in muscles which have been abused. There are severe pain and tenderness in all muscles, also a simultaneous restlessness which makes it difficult for the patient to rest or to relax. Fascicular twitching appears in the muscles and rapid atrophy ensues. During the acute stage the muscles are flaccid and deep reflexes absent; later the reflexes are normal. After a recovery period of several months the patient is able to be up and do moderate work, but he never recovers his former endurance. The author is probably the first to describe this syndrome. He reported 1 case in 1940 and 2 others in 1944. March described a typical case in 1943. The author describes 2 cases observed since the last report and 1 other case not correctly recognized eighteen years ago. The first patient presented here was a youth aged 16 who had done exercises demanding extreme exertion for three months, less for another four months. This was followed by sudden appearance of muscular tenderness, "jerking" of muscles, atrophy of upper limbs and of legs; extreme weakness approaching paralysis. The second patient was an arteriosclerotic man aged 61 who had hauled and lifted 539 cans of milk weighing 128 pounds each in three days. This exertion was followed by complete exhaustion, with loss of 27 pounds in six weeks in spite of rest. The third patient was dean of a university who worked fifteen to eighteen hours daily for ten years. He reached so low a level of endurance that walking two city blocks was sufficient to put him to bed for three weeks.

Topical Penicillin Therapy.—Sternberg and LeVan maintain that penicillin ointment is of value in a limited number of dermatoses ordinarily caused by penicillin-sensitive bacteria, such as impetigo, the ecthyma-pyoderma group, sycosis vulgaris and the infectious dermatitides. Inconsistencies in response to treatment occur, probably because of penicillin-resistant strains of streptococci and staphylococci and improper local use of the drug. The overall results of topical penicillin therapy of the bacterial infections of the skin are good, but comparable results have been obtained with other chemotherapeutic agents, although more time may be required. An appreciable number of persons are initially sensitive to penicillin. Studies have shown that a large but as yet undetermined percentage of people become sensitized to penicillin following local contact with the drug. Because of the increasing incidence of reactions concomitant with the present widespread use of penicillin, it seems likely that its topical use will eventually be limited to bacterial infections of the skin unresponsive to other therapeutic agents.

Neurologic Complications of Treatment with Rabies Vaccine.—Redewill and Underwood studied the files of the Los Angeles County Hospital for cases of rabies treatment reaction admitted over the last five years. The 5 cases reviewed presented mainly a neurologic clinical pattern and were true examples of complications due entirely to treatment with rabies vaccine. Recovery occurred in all 5 cases. One of the conditions most commonly confused with the neurologic reaction to rabies vaccine was anterior poliomyelitis. The onset a short time after initiating Pasteur treatment forms the main differential feature favoring the diagnosis given in these cases. Rabies itself, sometimes feared to be present at the onset, is ruled out principally by the clinical course; also the incubation period in cases complicating rabies vaccine treatment is usually between ten and seventeen days, that of rabies three to eight weeks. Complications may develop in persons never bitten by a rabid animal or exposed to rabies but who have merely been given Pasteur treatment. Many believe the reactions to be the result of anaphylactic or allergic action. The greatest number of accidents occurs with large doses of fresh virus, the lowest with the carbolized virus vaccines. It is possible that the fixed virus is the etiologic agent. The clinical entities included encephalitis alone and encephalitis with spinal involvement as well as pure spinal cord manifestations. Treatment was chiefly symptomatic. The incidence of complications does not warrant the withholding of the Pasteur treatment when indicated. The treatment is best suspended with the occurrence of neurologic symptoms.

Penicillin Production by a Thermophilic Fungus.—Rode and his associates say that a program for obtaining antibiotics from thermophilic organisms active against Brucella abortus is under way at the Brucellosis Research Laboratory at the University of Texas. Several fungi, actinomycetes and bacteria, all growing well at 52 C. and forming substances inhibitory to Brucella as well as to many other common test bacteria, have been isolated in pure culture from composted manure One of the fungus cultures is unique in that it produces penicillin at 52 C. and is a new species member of the group of penicillin-producing fungi. Heretofore the highest temperature for penicillin formation has been 37 C. The organism has been identified tentatively as Malbranchea pulchella. Of several mediums tests, corn steep liquor medium has given the highest antibacterial activity.

Alcohol Precipitation in Purification and Concentration of Influenza Virus.—Cox and his associates think that the widespread use of the chick embryo for the cultivation of viruses and the increased use of antigenic materials from this source for human vaccination make it desirable that influenza virus obtained from chick embryos be highly refined in order to eliminate or reduce the possibilities of sensitizing human beings to chick embryo proteins. The authors report experiments in which ethyl and methyl alcohol were used to concentrate and partially purify the PR-8 Weiss and Lee strains of influenza virus under carefully controlled conditions of alcohol concentration, temperature and p_H. Of the two, methanol was found to be superior, since the optimal concentration is of broader range, and less denaturation of viral protein is encountered than with ethanol. The data indicate that methanol precipitation under controlled conditions produces no virus denaturation nor loss of activity as judged by chicken cell agglutinating activity, infectivity titers in chick embryos or immunizing potency of killed vaccines for mice. On the contrary, based on the chicken cell agglutinating activity of the starting material, yields of virus equal to or exceeding 100 per cent are obtained. The methanol precipitation method is readily applicable to the concentration and purification of influenza virus using either the bucket, angle head or Sharples continuous flow types of centrifuges. The method is particularly valuable for producing vaccines on a large scale. The method may have application in the concentration and purification of other viral and rickettsial agents.

Reproduction and Lactation in Highly Inbred Strains of Mice on Synthetic Diets. P. F. Fenton and G. R. Cowgill.—p. 703.

Effect of Fat Level of Diet on General Nutrition.—Scheer and his associates found that, when young adult rats are subjected to severe caloric restriction on diets varying in fat content, weight loss is less rapid and mortality is less on diets containing liberal amounts of fat than on a fat free diet. During recovery from the period of caloric restriction, weight loss is more rapidly regained, and reproductive capacity is superior on diets containing fat. This is one of a series of studies on the importance of fat in the diet. In every instance animals performed more satisfactorily when fed diets containing liberal amounts of fat than when fed diets containing little or no fat. The observation of Forbes and his associates that the metabolic efficiency of food utilization is greater when fat is present suggests one important possible explanation. It does not seem that all the effects which have been observed on physical capacity, resistance to undernutrition, reproduction and lactation can be the result simply of increased efficiency of food utilization. It appears that fat must take an active part in a variety of fundamental vital processes.

Stress Incontinence.—According to Hock the causes and mechanism of stress incontinence in women are still poorly understood. Urinary continence is achieved by the sum total of all factors increasing the urethral resistance. Urinary incontinence develops if the sum total of these factors is decreased so that the urethral resistance is insufficient to withstand a sudden increase of the intravesical pressure. Reflex relaxation of the urethra is often a major factor in the causation of incontinence. If the relaxation is due to mechanical injury of the sphincters or supportive structures of the urethra, one of the accepted incontinence operations is indicated. If a reflex from some pelvic organ is responsible, correction of the disease will cure the incontinence. A frequent cause seems to be chronic inflammation of the urethral glands. In most cases a combination of several factors is at work. Usually there is some mechanical relaxation of the urethra which in itself is insufficient to produce incontinence. If reflex urethral relaxation is added, the combination of the two may lead to incontinence, and then clinical cure will follow the elimination of only one factor. If in the individual case it is impossible to determine whether incontinence is due more to mechanical or to reflex relaxation of the urethra, it is advisable to begin with the less risky treatment of the urethritis, which consists in urethral dilations and fulguration, the latter being especially effective. Twenty cases of stress incontinence in women and 2 cases of a similar condition in men are presented.

Urinary Calculi in Spinal Cord Injuries.—Prather is convinced that calculus disease in combination with renal infection is the most serious threat to those who have sustained injury of the spinal cord. His observations on this problem were made on over 60 patients with injury of the spinal cord in an army general hospital in this country. Intravenous urography was employed as soon as possible after admission as a part of the routine study, and the urograms were repeated at intervals of six to eight weeks, or more often if a febrile episode arose. Over a period averaging fifteen months from time of injury the author found an incidence of 31.5 per cent of renal calculi in patients with complete transection of the spinal cord and an incidence of 20 per cent in those with partial transection. Bladder calculi also were common. Of the patients with complete transection 30 per cent either had bladder calculi at the time of admission or developed them during hospitalization. Only 14 per cent of those with partial transection were found to have bladder calculi. These findings may be explained by the longer period of bladder drainage which was commonly necessary in patients with complete transection of the spinal cord. Formation of bladder calculi occurred irrespective of suprapubic or urethral catheter drainage, irrespective of tidal (automatic) or a manually controlled irrigation, and during the use of solution M as the sole irrigating medium. In most instances the calculi were small and could be removed with the cystoscopic lithotrite and with the aid of the Ellik evacuator and resectoscope sheath. Analysis showed that the stones from the kidney and the bladder were principally calcium phosphate and calcium carbonate. In the absence of a generally effective prophylaxis of calculus formation, surgical treatment frequently is necessary.

Hearing Aid for Relief of Tinnitus Aurium.—Saltzman and Ersner state that the fenestration operation will restore hearing and afford relief from tinnitus in a large percentage of cases of otosclerosis. This surgical procedure makes a path for extraceptive sound to reach the inner ear and by doing so the patient's intrinsic tinnitus either is subdued or becomes tolerable. The benefits obtained from a hearing aid are analogous to those of the fenestration operation. By amplification, much outside sound is enabled to reach the cochlea, crowding out and masking the patient's head noises. It was in the routine fitting of hearing aids that the authors discovered the therapeutic advantages in regard to tinnitus. They found it most efficacious in otosclerosis for those patients who are not suitable for the fenestration operation or are unwilling to undergo it. In nerve deafness, if no extraordinary tolerance difficulties are present, a hearing aid will afford considerable relief from head noises simultaneously with improvement in hearing. A hearing aid is helpful also in the tinnitus associated with chronic adhesive otitis media.

Family Epidemic of Infectious Hepatitis.—An epidemic of infectious hepatitis occurring in 9 of 10 children in a single family was followed by Kunkel and Hoagland for five months in New York. The children ranged in age from 3 to 20. Contact was found to be the probable mode of spread. Determinations of sulfobromophthalein retention and thymol reactivity of the serum proved to be valuable aids in the detection of nonicteric cases. The thymol turbidity test, because of its prolonged elevation, was of special value in an epidemiologic study. Spider angiomas, which developed during the acute attack, were found in 5 cases. This physical sign was characterized by sudden onset and delayed disappearance. It proved to be helpful in corroborating the diagnosis in 2 cases. Six children did not develop clinical evidence of jaundice. The severity of the illness and the presence of jaundice showed a definite relation to the age of the children, the disease being milder in the younger group.

Massive Gastrointestinal Bleeding Following Exposure to Low Pressure.—A medical officer aged 29 was admitted to a station hospital because of bloody diarrhea of two days' duration. Two days before admission the patient had been exposed to a simulated altitude of 41,000 feet while demonstrating some of the phenomena of high altitude physiology. During the reduction in pressure he had crampy abdominal pain with distention. This was mild at first but increased during the ten minutes at that pressure. The pressure was then increased to 2¾ pounds per square inch—equivalent to an altitude of 39,000 feet. This was maintained for half an hour. The abdominal pain was not disabling but was uncomfortable. It disappeared during the increase in pressure. He ate supper and went to bed early. About four hours after retiring he was awakened with crampy abdominal pains that were generalized and associated with a desire to evacuate. A large bloody diarrhea containing dark clots ensued. Three hours later similar rectal bleeding occurred. The next day the patient felt well and went about his daily duties. Three more tarry stools in the next twenty-four hours brought him to the hospital. On the fifth hospital day the stools became normal. Schier discusses the differential diagnosis and possible etiologic factors, namely shock, acute dilatation and air embolism of the bowel and increased capillary permeability associated with an allergic diathesis. Other possible sources of bleeding of an obscure nature are discussed, including Meckel's diverticulum and new growths of the small intestine. Treatment is symptomatic, with early transfusion. Surgery is indicated when the source of the bleeding is definite and the lesion is remediable by surgery or when severe recurrent hemorrhages of unknown nature leave surgery as the only resort.

Body Snatchers. J. Grindle.—p. 627.

Homologous Serum Hepatitis.—In commenting on homologous serum hepatitis, which occurred in 5 men between 48 and 63 and in 1 woman aged 31, Schiff emphasizes the importance of homologous serum jaundice in the differential diagnosis of jaundice, with particular respect to (1) metastatic neoplasm of the liver in patients who have had a recent resection of a malignant tumor, (2) stricture of the common duct (or sometimes stone) in patients who have had a recent operation on the biliary tract, usually a cholecystectomy, and (3) neoplasm as a cause of painless jaundice in middle aged or older persons. It is essential to keep homologous serum jaundice in mind whenever a patient with icterus is seen, regardless of the age of the patient, particularly if there is a history of an illness or an operation two to five months before the development of jaundice, even if the operation was performed on the biliary tract. Suspicions should be confirmed by recourse to the cephalin cholesterol flocculation and thymol turbidity tests.

Echinococcic Infection.—Swartzwelder reports 15 instances of echinococcic infection in 7 men and 8 women between the ages of 22 and 72 years. All 15 occurred in Louisiana. Ten of the 15 patients, 4 of whom were Negroes, were born in the United States. This suggests that human infection with this endemic disease may be acquired in this country. Whereas echinococcic infection has been found more often in native born residents of Louisiana than in immigrants, 95 per cent of the total number of patients with hydatid disease reported from the United States and Canada prior to 1940 in whom the nationality was known were immigrants. The value of employing intradermal and complement fixation tests with either sterile hydatid fluid or substitute tapeworm antigens in an effort to provide a diagnosis prior to operative procedure is emphasized.

Respiratory Tract Infections.—Baetjer discusses the methods which industry may adopt in an effort to prevent the spread of diseases of the respiratory tract among workers. These diseases are the most important cause of absenteeism due to sickness. Since they originate from persons who have the disease-producing organisms in their nose and throat, the most important preventive measure is good personal hygiene to avoid the dissemination of such organisms into the air. Paper handkerchiefs may be supplied to employees to be used when sneezing, coughing and blowing the nose and then to be placed immediately in receptacles. To prevent droplet infection a distance of a few feet should be allowed between workers who face one another. Oiling of floors is of value in preventing bacteria and other organisms, which settle to the floor, from again contaminating the air. Proper sanitation in the preparation and serving of food is essential. Studies made by the army have shown that the recently developed vaccine against the influenza virus types A and B will greatly reduce the incidence of these diseases. Since the duration of the immunity resulting from this vaccine has not been determined and since epidemics of influenza cannot be accurately forecast, it would seem better not to urge vaccination in anticipation of an epidemic. The continuous administration of sulfonamides for prophylactic purposes may lead to drug resistance and thence to epidemics of these infections. Experiments have shown that neither irradiation with ultraviolet light nor the addition of vitamins to an ordinary diet will increase the resistance of industrial workers to infections of the respiratory tract. Measures to protect against the chilling of the body are important.

Exposure to Tellurium.—Amdur reports accidental single exposure of 3 previously healthy young men to tellurium fume. The total period of exposure in the experimental laboratory was approximately ten minutes. All 3 experienced transient headache and slight epigastric distress within twenty-four hours of their exposure. All 3 were aware of a metallic taste in their mouth. There was no nausea or emesis and nothing to suggest loss of blood from any of the body orifices. The most notable complaint was that of a prominent obnoxious garlic odor present on the breath and in the sweat and presumably due to the detoxification product, dimethyl telluride. Heretofore it has been as protracted as it has been persistent. All 3 patients were given injections of BAL in oil, 2.5 mg. per Kilogram of body weight, deep intramuscularly into the buttock every four hours for the first twenty-four hours and every six hours for the second period of twenty-four hours. Treatment was continued with one injection daily for the ensuing six day period. In 2 patients the garlic odor on the breath and in the sweat had disappeared fourteen days after exposure and in 1 patient thirteen days after the exposure. It is suggested that tellurium may be added to the list of metallic exposures successfully treated with BAL.

Rickettsialpox.—Huebner and his associates state that Rickettsia akari, the causative agent of rickettsialpox, was isolated from the blood of persons with this disease and from the rodent mite Allodermanyssus sanguineus Hirst inhabiting the domicile of persons who were ill. The authors isolated R. akari from a house mouse trapped on the same premises—a housing development in the city of New York where more than 100 cases of rickettsialpox have occurred. Infestations of house mice with the mites were described in a previous communication. The ability of A. sanguineus to transmit rickettsialpox to experimental animals was demonstrated. The data presented show that the house mouse (Mus musculus) may harbor the infection in nature.

Plague: Field Surveys in Western United States.—Wayson says that investigations of the circumstances surrounding the death of 2 persons from bubonic plague in July 1908 in a semirural area bordering San Francisco Bay revealed an enzootic of plague among the California ground squirrels. This discovery stimulated explorations to determine the extent to which the infection had spread. Investigations of the circumstances which may influence the epizoology and epidemiology of plague have been carried on concurrently in the field and in the laboratory. All of the laboratory studies confirm previous findings that Pasteurella pestis exhibits consistent characteristics which do not permit differentiation of strains recovered from rats, from other rodents, from fleas or from man. These investigations have also established that each of a number of species of fleas may serve as vector of the disease for different rodent hosts. Foci of bubonic plague among rodents of several genera are widely scattered throughout the area within the north and south boundaries of the United States and from the Pacific Ocean to approximately the 102d meridian west. The rapidity of extension eastward will probably be influenced by the density of the rodent populations and the persistence from year to year of foci in which acute outbreaks recur. An element of chance enters into the fulfilment of conditions favorable to the progressive spread of the disease. It has been disseminated over large areas of the United States, and the possibilities of its introduction into new areas through migrations and through the channels of commerce and transportation are deserving of continuous attention.

Venous Catheterization of Heart.—Sosman reports the results of 100 examinations for congenital heart disease, other forms of heart disease, pulmonocardiac disease and renal function. The technic of heart catheterization is illustrated by roentgenograms. The comfort of the patient is important for the success of the test. Teamwork is essential. Failure to secure adequate or reliable data from this test has been infrequent; only 13 examinations out of 100 were unsatisfactory. Spasm of the vein around the catheter in the arm may prevent passage to the desired spot but has not interfered with withdrawal of the catheter. Venospasm is more apt to occur if the patient is uncomfortable or in pain. When trying to pass the tip of the catheter through the tricuspid valve, ventricular extrasystoles occur in about half of the cases. A few have mentioned an accompanying sensation of tightness in the substernal area or neck. In only 2 instances were the subjective symptoms distressing enough to cause abandonment of the procedure. The dangers most commonly feared are damage to the endothelium of the large veins or of the heart and the possibility of thrombus formation, but no thrombi have been formed. Some patients succumbed to their disease or conditions unrelated to the procedure, and in necropsies no trace of damage could be found.

Value of Catheterization of Heart.—Dexter describes experiences with catheterization of the heart in representative types of congenital heart disease. He concludes that, in order to obtain interpretable results in congenital heart disease, venous catheterization must be performed by a well trained team of at least three persons working smoothly and efficiently, and it should be used in conjunction with the usual procedures of history, physical examination, electrocardiography, fluoroscopy and, if available, the Robb-Steinberg technic of visualization of the cardiac chambers with diodrast. Venous catheterization is essentially a physiologic procedure and has certain limitations. Now that cure or improvement of certain congenital cardiac defects is possible by surgery, venous catheterization promises to be an important aid in preoperative diagnosis.

Cerebral Angiography and Intracranial Neoplasms.—List and Hodges say that in a series of 125 patients with intracranial tumor subjected to angiography at the University of Michigan Hospital a special vascular pattern was observed in angioma, meningioma, glioblastoma and certain types of astrocytoma. Although a characteristic pattern is not always to be found, the angiograms often are so characteristic as to permit a preoperative anatomic diagnosis.

Surgical Treatment of Hypertension.—De Takats and Fowler report the results of splanchnic nerve section on 19 patients with hypertension. Eleven were females between the ages of 7 and 46 years and 8 were males between 13 and 39. The patients have done well, moderately well and poorly. The operation, a transdiaphragmatic approach, technically left nothing to be desired. The clinical history and renal biopsies made it possible to separate a group of patients who suffered organic renal damage and showed good response to surgery. The so-called neurogenic group (4 of the 19 patients) failed to respond even though there was little or no detectable damage. It is suggested that such hypertension exhibits a hypothalamic-pituitary stimulation which is not mediated by the sympathetic nervous system.

Ambulatory Treatment of Phlebitis.—In the treatment of acute and chronic phlebitis of the legs, Meyer has used for fifteen years the elastic combination bandage. It consists of a 4 inch wide, moist, medicated, viscous, nonsetting, zinc-gelatin type (contura) bandage and a 3 inch wide, elastic, adhesive pressure (pressoplast) bandage. The elastic adhesive bandage is used for compression and grip. By applying a strong and even pressure around the leg to a point above the inflamed vein one succeeds in compressing the dilated veins, thereby restoring function of the valves and normal circulation. The pressure also promotes the absorption of existing thrombi and prevents their detachment from the walls of the veins. The restoration of the circulation prevents formation of new thrombi and removes the swelling. After application of the bandage the patient is told to walk as much as possible, at least 3 miles daily, and to avoid standing. The bandage is changed at first every third day and later twice a week. The treatment cures the phlebitis in the leg by eliminating the venous congestion, thereby removing the locus minoris resistentiae and making it possible for the affected tissues to overcome the infection. The treatment must be supplemented with removal of primary foci in the oral cavity and secondary foci in the jugular veins to prevent reinfection of the veins of the leg.

Retrograde Saphenous Vein Ligation and Phlebectomy.—According to Vaughn, varicose veins may recur after high saphenous ligation combined with retrograde injection. This recurrence following adequate surgery in the femoral triangle may be due to incompetent communicating or perforating veins, which hastens recanalization of the thrombus in the saphenous. Retrograde ligation and excision of segments of the saphenous vein at different levels above and below the knee should interrupt any reverse flow of blood which might come from incompetent communicating or perforating veins higher up. A medium size malleable intraluminal guide facilitates finding the saphenous vein both above and below the knee and many times in locating an incompetent communicating or perforating vein or aneurysm. A small piece of umbilical tape rolled on itself and attached to a hemostat facilitates dissection of the vein. Longitudinal incisions are superior to transverse incisions in retrograde saphenous ligation and phlebectomy. Retrograde ligation and excision are to be considered superior to retrograde injection.

Penicillin and Bone Grafts in Infected Skulls.—McCorkle and his co-workers produced infected bone defects in the skulls of dogs, contaminating the wounds with street dirt. After the chronic infections had become well established the animals were subjected to operations at which granulations, scar and sequestrums were removed, bone grafts placed in the skull defects and the wounds closed in layers with cotton sutures without drainage. Ten animals were used as controls and the other ten were given 100,000 units of penicillin daily for two days preoperatively and for twenty-one days postoperatively. In the animals treated with penicillin there was satisfactory healing of soft tissues, survival of the bone grafts and union between graft and skull in the presence of both penicillin susceptible and penicillin resistant organisms. These results appear significant when contrasted with the suppuration of the soft tissues and absorption or loss of grafts that occurred in most of the untreated control animals.

Management of Early Syphilis.—Smith stresses that a large percentage of cases of early syphilis are not cured by penicillin, regardless of dosage. The relapse rate with all short rapid treatment schedules is high. Therapy should be continued for at least eight to twelve weeks in early syphilis, using penicillin, arsenic and bismuth.

Phrenic Paralysis in Treatment of Pulmonary Tuberculosis.—Alley and Hubbard say that phrenic paralysis is not being employed extensively in the treatment of pulmonary tuberculosis. They wish to stimulate more interest in the use of this method because there is often much to be gained by the use of this procedure and seldom anything is lost by giving it a trial. The procedure used by the authors was to crush the main phrenic trunk, or trunks as are sometimes found, and to resect all accessory phrenic trunks from the fifth cervical root, including the nerve to the subclavicus muscle. If permanent paralysis of the diaphragm was desired, 1 to 2 centimeter sections of all main phrenic trunks as well as the accessory were taken. A study of results obtained from 765 operations on 627 patients indicates the therapeutic value of the procedure and strengthens the belief that phrenic paralysis should receive more consideration in the treatment of pulmonary tuberculosis.

Eosinophilic Granuloma of Bone.—Cooley and Carlson say that, since the introduction by Lichtenstein and Jaffe in 1940 of the term eosinophilic granuloma of the bone, considerable information has been gathered about this condition

The authors report observations on 10 patients seen in military hospitals during the last three years. The patients complained of pain or discomfort in the region of the bony lesions. Localized tenderness was usually present at the onset but decreased after a period of weeks. Six of 10 patients showed localized soft tissue swelling. Constitutional symptoms were usually absent. Eosinophilia was seen in only 1 of these patients and that was after roentgen therapy.. In the x-ray studies the osseous lesions often simulated Schüller-Christian's syndrome. The configuration of the defect was typically round or oval, sometimes cloverleaf, representing bone destruction with replacement by radiolucent granulomas. This created a "punched out" appearance. Most cultures of the curetted material were sterile. Pathologic studies were incomplete, since there have been no deaths. The white or yellowish granulations separated quite easily from the bone and left a slightly roughened margin. A combination of surgical and radiation treatments seemed to produce the best therapeutic results.

Brenner Tumor of Ovary.—Andujar and his co-workers report observations on Brenner tumor occurring in 2 women aged 72 and 64. In each instance hyperplastic endometrial changes were present, in 1 patient of polypoid type, in the other patient of simple Swiss cheese structure. Both patients were relieved of their uterine bleeding by operation. In 1 instance relief followed removal of a large Brenner tumor; in the other it occurred after excision of both the ovarian tumor and the uterus. In view of the continued failure to report hormonal activity of Brenner tumor, the association of hyperplastic uterine bleeding with these tumors is probably purely coincidental. Brenner tumor is probably far more common than one would suppose from the few cases thus far reported.

Emotion in Relation to Illness.—According to Caveny the practitioner of medicine encounters few medical or surgical problems which do not have a psychosomatic component. Instincts as well as personal desires and ideas are constantly being checked and subdued by environmental, educational and social influences. These opposing forces give rise to conflict. If adjustment is faulty, the individual takes recourse to anxiety, headaches, nausea and vomiting. Persons with psychosomatic ailments do not always show manifest symptoms of emotional imbalance; therefore the psychic factors often remain undetected, and this may delay or prevent recovery. Until recently most physicians believed that only gastrointestinal conditions, as peptic ulcers and colitis, could be considered to be psychosomatic. The emotions are now regarded as the primary cause in many cases of bronchial asthma, hay fever, hypertension, heart disorders, the common cold and various dermatologic conditions as hives, warts and allergic reactions, as well as many other physical illnesses. If the emotions are not the primary cause they may be a precipitating or aggravating factor. The general practitioner's job is prophylactic, therapeutic and morale building. He accomplishes this aim by maintaining a philosophy of medicine which makes for a full knowledge of the sick man, a person whose illness may have a social implication. Even though the practitioner appears to perform his job intuitively, he possesses considerable knowledge of psychiatry and the psychosomatic approach as well as the basic principles of psychotherapy.

Analysis from 873 Electroencephalographic Examinations.—Rossen correlates the results of 873 electroencephalographic examinations with the admission and discharge diagnoses of neuropsychiatric patients studied at a United States naval hospital. Of the 226 discharged with the diagnosis of epilepsy, 50 per cent showed abnormal electroencephalograms and 19.9 per cent showed slightly abnormal electroencephalograms. Of the remaining 647 cases with other discharge diagnoses, which included various functional neuropsychiatric and organic neurologic conditions, 18.4 per cent had abnormal electroencephalograms and 20.7 per cent had slightly abnormal electroencephalograms. From comparisons with control series it appears that clinical neuropsychiatric evaluation is at present superior to electroencephalographic examination alone in determining qualification for military service except in convulsive disorders. This is in agreement with other investigators, who thought that the use of electroencephalography in screening army entrants or soldiers who have suffered neurotic breakdown should be engaged in with the utmost caution.

*Studies on Human Artificial Insemination. A. I. Weisman.—p. 348.

Circulation Time in Differential Diagnosis of Thyroid Disease.—Hay used calcium gluconate for the estimation of the circulation time. He compared the circulation time, basal metabolic rates and blood cholesterol levels of 40 patients with abnormalities of the thyroid, 30 with toxic goiter, 5 with myxedema and 5 with nontoxic adenomatous goiter. The patients with myxedema had a minus basal metabolic rate and a prolonged circulation time. Those with nontoxic adenomas have normal metabolic rates and circulation times. Most of those with toxic thyroids had a high basal metabolic rate and short circulation time. Not all patients with toxic goiters have the classic signs and symptoms; 30 per cent are seen to have either a normal basal metabolic rate or a normal circulation time. It is in these cases that multiple tests are helpful in establishing the diagnosis. In 17 per cent of the cases the circulation time was within normal limits and the basal metabolic rate was elevated. In 13 per cent of the patients the basal metabolic rate was normal and the circulation time short. Here the circulation time was more valuable in the diagnosis. In only 70 per cent of toxic goiters were the basal metabolic rate and the circulation time both diagnostic, and in only 60 per cent of the cases were all three—the basal metabolic rate, circulation time and blood cholesterol—diagnostic. The author makes a plea for multiple tests in evaluating toxic goiter, at least in the borderline cases. The circulation time is not a substitute for clinical evaluation or any other helpful tests in the diagnosis of toxic goiter. It was not a good criterion for determining the optimal time of operation in this series.

Human Artificial Insemination.—Eighty-seven apparently fertile women whose husbands were definitely sterile were inseminated artificially with donor semen over a period of seven years. Seventy-four of the women became pregnant. Follow-ups of the successful cases revealed that children conceived by this method were physically and mentally as sound as children produced by the natural method. Weisman says that the most valuable finding of the follow-up survey was the healthy psychologic relationship of the family unit having a child derived through artificial donor insemination.

Transmission of Endameba Histolytica by Musca Domestica.—A survey of the literature and experiments convinced Roberts that a fly given access to infected material may transmit Endameba histolytica cysts in its feces. Experiments have shown that the period during which the fly can be regarded as a source of infection by this route may extend from five minutes to at least thirty-one hours after the initial infective feeding—the limit of the observations—and that during this period cysts are excreted in considerable, though irregular, numbers. Studies on the part played by the vomit drop in the spread of E. histolytica cysts prove that E. histolytica cysts taken up by house flies during the act of feeding subsequently appear in their vomit drops at irregular intervals and in irregular numbers throughout an observation period of nine hours after the initial infective feeding. The route taken by the cysts occurring in the vomit drop has not been definitely ascertained. It is generally believed that in urban areas polluted drinking water and food handlers are the main sources of infection with amebic dysentery. In rural areas, particularly in the tropics, flies may prove of greater importance, for, under such conditions, not only do they tend to occur in greater numbers but, owing to lack of sanitation, they have readier access to infected excreta and to human food supplies.

Tropical Eosinophilia in East Africa.—According to Wilson the syndrome now generally known as tropical eosinophilia or eosinophilic bronchitis was first described by Frimodt-Möller and Barton in southern India in 1940. Weingarten in 1943 reported 81 cases of tropical eosinophilia. While tropical eosinophilia can no longer be regarded as a rare disease in India and Ceylon, its existence in Africa has not yet been generally recognized, although isolated cases have been reported. Wilson performed differential white blood cell counts on a consecutive series of 34 patients attending the native civil hospital in Dar-es-Salaam, Tanganyika, with symptoms of recurrent bronchitis or asthma. In 6 the eosinophilia ranged from 40 to 78 per cent. This group and a seventh patient referred on account of an unexplained eosinophilia were submitted to detailed investigation. All had tropical eosinophilia. Six were treated successfully with arsenic, while the seventh recovered spontaneously. The characteristic picture appeared to be recurrent attacks of cough, wheezing and low fever separated by intervals in which the only symptom was a spasm of unproductive coughing in the morning. The etiology of tropical eosinophilia remains obscure. Löffler in 1936 described a syndrome characterized by fever, cough and eosinophilia which resembles tropical eosinophilia but seldom lasts more than eight days, whereas tropical eosinophilia, if untreated, may persist for years. It seems unlikely that the two conditions are identical. The detection of tropical eosinophilia in 6 of 34 patients with chronic cough or asthma suggests that the condition is relatively common in East Africa.

Causalgia of Face.—Bingham observed 2 cases of causalgia of the face. The first patient had sustained a small penetrating wound of the right cheek. Burning pain on the right side of the face developed on the day he was wounded and was still present a year later. Hyperalgesia of the skin supplied by the three divisions of the trigeminal nerve was present. The facial pain was completely relieved by a procaine block of the stellate ganglion. When the pain returned, it was decided to excise the superior cervical sympathetic ganglion. This operation relieved the facial pain and tenderness, and there was no sign of their return three months later. In the second patient, who had sustained multiple mortar wounds on the side of the face and head, there developed a continuous burning pain, usually confined to the maxillary division of the trigeminal nerve. In this patient the lower half of the superior cervical ganglion and a portion of the sympathetic chain were excised, and facial tenderness and pain were relieved.

Bacteriologic Studies on Food Containers.—Outbreaks of food poisoning induced Knox and Walker to investigate bacteriologically the conditions in a central meals kitchen from which about 3,000 meals were issued daily. Plate counts showed that the containers in which the meals were sent out contained large numbers of organisms, from several thousand to several hundred thousand. Counts of this order were obtained both before and after the routine method of washing. These counts were reduced to the order of a few hundred or less per container by steam sterilization. Exposure for two to three minutes to steam from a simple jet sterilizer was effective for all except large insulated lids, which required at least five minutes. Treatment for five minutes in a chamber filled with steam from a boiler was effective with all types of containers and lids tested. If containers are to be sterilized at all, they must be sterilized each time they are to be used. Counts almost as good as those given by steam sterilization were obtained by washing with soap and water at 48 to 50 C., wiping with a sterilized dish cloth and then rinsing in a second sink of water at 75 to 80 C.

Prenatal and Postnatal Development of Immunity.—Rimington and Bickford point out that little is known about serum protein levels of infants and their mothers at and before parturition. The present investigation was undertaken to fill this gap and so provide a basis for a possible relation between susceptibility to neonatal infections and the degree of development of the protein elaborating mechanisms. Determinations were made of the total protein, nonprotein nitrogen, albumin and globulin in the maternal and cord blood from 38 cases, mainly of premature birth, the youngest fetuses being 20 weeks old. The fetal albumin and globulin increase with the length of gestation and at about the same rate Mean full term values were 4.16 Gm. per hundred cubic centimeters for albumin and 2.37 Gm. per hundred cubic centimeters for globulin. The maternal albumin and globulin are not affected by the length of gestation and are only slightly correlated with the fetal values. It is suggested that there may be a fetal mechanism of synthesis of both albumin and globulin which becomes relatively less important as the adult mechanisms of synthesis develop and take its place. The serologic immaturity of the newborn would be understandable on this basis.

Residual Action of DDT Against Gambiae and Funestus.—The experiments described by Hocking were undertaken to provide guidance in the practical employment of DDT impregnation as an antimalarial measure in the East Africa command. It is concluded that Anopheles gambiae and Anopheles funestus tend to leave a lightly treated building, but that with an impregnation of about 200 mg. per square foot final mosquito mortality approaching 100 per cent will be achieved and that on most surfaces the effect will last for at least four to six months. Limewash, particularly if recently applied, neutalizes the residual action of DDT on walls.

Monkeys in Relation to Yellow Fever in Uganda.—Haddow and his associates say that for several years studies on the epidemiology of yellow fever have been conducted in Bwamba County, Uganda. The work has included the collection of blood samples from wild monkeys for examination by the protection test. Many other groups of animals also have been investigated, but so far immunity to yellow fever has been found only in monkeys. Twelve species and subspecies of monkeys have been found to occur in Bwamba. In addition there are two members of the suborder Lemuroidea. It is suggested that the lowland colobus monkey (Colobus polykomos uellensis Matschie) is the main species involved in the monkey to monkey yellow fever cycle of the uninhabited forest areas, that the redtail (Cercopithecus nictitans mpangae Matschie) plays an important part in bringing the virus into contact with man and that the remaining species are of less importance in the local epidemiology. In Bwamba the susceptible monkey population becomes immunized at the rate of 27 per cent annually. This observation, in conjunction with other evidence, indicates that yellow fever is truly endemic among the monkeys of the Bwamba lowlands.

**Genitohypophysial Reflex and Ovulation. R. Segond.—p. 359.*
Penicillin Treatment with Delayed Elimination. M. Morgenstern and A. Grimberg.—p. 360.

Genitohypophysial Reflex and Ovulation.—According to Segond, stimulation of the genital sphere brings into play a neuroangiotropic reflex which itself is to be considered as generator of a pituitary glandular action on the ovulation. Stimulation of the superior cervical ganglion induces hypophysial secretion of the follicle stimulating and luteinizing factors of anterior pituitary-like principle. The deficiency of the gonadotropic pituitary-like principle may be considered responsible for lack of ovulation. Laboratory proof of this concept was furnished: During the first eight days of the cycle pituitary hormone was not demonstrable in the urine; the absence of this secretion was confirmed by a negative test on mice not arrived at puberty. Stimulation at the level of the uterus (dilation of the cervix, lipiodol) was carried out, followed next morning by a repeated search for chorionic gonadotropin in the urine. This time the test was positive: there was macroscopic evidence of the development of the genital tract and of follicle growth on the surface of the ovary, confirmed by microscopic demonstration of numerous ripe follicles. Any treatment of sterility in women must be directed to ovulation by the reflex route producing a genitohypophysial reflex. Numerous pregnancies resulted from cervical dilation on the sixth day of the cycle repeated at the same date for three months, but the whole procedure had to be repeated again for each new pregnancy.

*Cancer of Stomach in First Two Decades of Life. P. Funck-Brentano and R. Tubiana.—p. 1171.

Cancer of Stomach in Children and Adolescents.—Funck-Brentano and Tubiana report cancer of the stomach in a boy aged 15. Subtotal gastrectomy of the Polya type was performed. Microscopic examination revealed an ulcerated epithelioma with multiple metastases of lymph nodes. The boy was alive six months after the operation; he had gained weight and had no complaints. Analysis of 92 cancers of the stomach in children and adolescents less than 20 years of age reported in the literature demonstrates that the condition is extremely rare under 20 years of age but ceases to be exceptional over 20. Sixty-nine of the 92 patients had epithelioma, 17 had sarcoma and 6 had Krukenberg tumor. Epithelioma is the least rare in children and adolescents, as it is in adults. The symptomatology of cancer of the stomach is polymorphic and does not differ from that in the adult. Roentgenography offers considerable aid to diagnosis. Interpretation of the roentgenograms should be made without regard to the age of the patient. Gastrectomy is the preferred method of treatment. The risk of postoperative anemia does not seem important in spite of the youth of the patients operated on.

Local Penicillin Treatment in Diphtheria.—Gut used local penicillin therapy in the form of a spray. At first she used a concentration of 250 units per cubic centimeter, but later the concentration was increased to 1,000 units. There was no difference in the efficiency of these two concentrations. The spray was applied three times daily on the pharynx and tonsils, as well as into the nostrils. Of the 45 patients treated, 26 had pharyngeal diphtheria and 19 were bacillus carriers. The local penicillin therapy of diphtheria patients and of carriers resulted in a noticeable shortening of the period of isolation: freedom from bacilli was achieved within thirty days in 71 per cent of the patients, whereas this occurred in only 25 per cent before penicillin was used. Penicillin therapy is given in addition to serum therapy, not in place of it. In the severest cases penicillin can be given also parenterally.

Sedimentation Rate of Erythrocytes Following Injection of Own Blood.—Ruge points out that the erythrocyte sedimentation rate, which is determined by the amount of coarse disperse colloids in the blood, shows certain fluctuations, depending on the tissue destruction and the rapidity of transition into the blood stream. Injection of a person's own blood (autohemotherapy) increases the permeability of the capillary endothelium and facilitates the exchange of tissue and blood colloids. In healthy subjects the fluctuation caused by autohemotherapy never exceeds 20 per cent. Higher accelerations of sedimentation rates following autohemotherapy indicate that the colloid content of the tissue exceeds that of the blood. In this manner foci of infection can be disclosed. In infectious diseases the comparative sedimentation rates before and after injection of the person's own blood permits a more exact prognosis in that it can be learned whether the disease process is increasing or receding. Especially in articular rheumatism, tuberculosis and after carcinoma operations the comparative sedimentation rates permit a more exact prognosis than does the simple sedimentation reaction.

Importance of Retrograde Pyelography in Diagnosis of Paranephritic Abscess. H. Mäder.—p. 560.

Diagnostic Value of Wohlgemuth's Reaction in Acute Pancreatitis.—Most surgeons agree that when acute pancreatitis does not result in abscess formation it should be treated conservatively, since surgical intervention may make the prognosis even more unfavorable. If a patient complains of severe continuous pain in the upper part of the abdomen, chiefly on the left side, with possibly radiation to the left shoulder, if there are signs of shock with intestinal intoxication, if the vomit contains water and bile but no fecal material, if there are sweating and cyanosis of the extremities, small pulse, lowered blood pressure and hypothermia and if there is a history of biliary disturbances, acute pancreatitis should be thought of. The differential diagnosis must rule out cholelithiasis, ileus, gastrointestinal perforation, ruptured appendix, angina pectoris, mesenteric thrombosis and renal disorders on the left side. If these conditions have been ruled out and the determination of the diastase in the urine according to Wohlgemuth's method reveals increased values, the diagnosis of acute pancreatitis is almost certain. Since Wohlgemuth's test has a failure rate of about 20 per cent, it can be relied on only in connection with the clinical picture. The author also mentions the occurrence of hyperglycemia and excessive elimination of insulin in acute pancreatic disorders and stresses that in future these incretory disturbances should be watched for in addition to the urinary diastase values.

Medical Prophylaxis of Silicosis.—Stucki cites the high compensation payments for patients with silicosis as an indication of the seriousness of this problem in Switzerland. In 1945 compensation payments to persons with silicosis were more than eight times as high as for all other occupational diseases. A decree of the Swiss Federal Council concerning silicosis in miners and in men who blast tunnels has made medical prophylaxis of silicosis obligatory. The fact that men who blast tunnels never remain very long in the same vicinity makes continued observation difficult. For this reason the author emphasizes the necessity of a central organization for the prophylaxis of silicosis which could be arranged and supervised by the Swiss accident insurance organization.

*Primary Cancer of Gallbladder. H. Larre.—p. 768.

Primary Cancer of Gallbladder.—Cancer of the gallbladder was associated with biliary lithiasis in 7 out of 9 cases reported. Clinical diagnosis was made too late for effective treatment. Cholecystectomy improves the prognosis if it is performed in the precancerous stage. Microscopic examination of frozen sections of the removed gallbladder should be routine. Removal of the gallbladder bed is necessary if cancer cells are found in the sections.

*Diet in Therapy of Typhoid. M. A. Landa Bacallao.—p. 107.

Diet in Treatment of Typhoid.—Forty patients with typhoid were given a liberal, well balanced, mixed, high calory diet rich in vitamins and minerals. Two patients died. The febrile period varied between twenty and thirty days. Nervousness, mental symptoms and insufficient peripheral circulation, which frequently appear in the course of a liquid diet, did not appear in the course of this treatment. Hemorrhage occurred in only 1 patient. Transient recurrence was observed in 2 patients. Convalescence was shortened to one week in the majority. The nutritional condition after the disease was good. The results of treatment with a liberal diet are encouraging.

*Clinical, Roentgenologic and Histopathologic Contribution to Study of Pancoast Syndrome. G. Fregonara.—p. 504.

Pancoast Syndrome.—Fregonara reports 4 cases of Pancoast syndrome in men between the ages of 27 and 51. A primary tumor of the lung with metastases in the cervical lymph nodes was demonstrated on microscopic examination in 1 case, and clinical and x-ray observations were suggestive of primary cancer of the lung in 2 cases and of a secondary neoplasm with metastasis taking place from a previously removed tumor of the testicle in 1 case. All patients presented pain in the scapulohumeral region and in the lower cervical and upper dorsal regions. The entire Horner syndrome was present in 3 patients and partly in 1. Opacities were demonstrated on x-ray examination in the apexes of 3 patients. Skeletal changes of osteolytic type were present in the initial stage of the disease, and total destruction of the costal segments of the posterior wall in the final stage. Coutard's method of roentgen irradiation had only a temporary effect on the severe pain.

Rh Factors and Blood Transfusion.—Tischendorf reports that complications developed in 3 patients after transfusion of Rh positive erythrocytes to Rh negative recipients. The first patient, a woman aged 41 with the typical signs of hemolytic spherocytic anemia, developed a severe hemolytic reaction following transfusion of 300 cc. of Rh positive blood. This woman had typical congenital hemolytic icterus, the hereditary character of which was proved by the fact that a brother had undergone splenectomy for the same condition. The complication following the blood transfusion became manifest as an alarming febrile hemolytic reaction with increase in anemia. It was the result of the action of the anti-Rh agglutinins of the Rh negative recipient on the Rh positive erythrocytes of the donor. The second patient, a woman aged 26, also had a typical hemolytic spherocytic anemia. The woman had had a subicterus five years previously, when hemolytic icterus had become manifest with the symptoms of cholelithiasis. Pregnancy complicated the icterus, and when the hemolytic anemia progressed following a blood transfusion (Rh factor of donor not determined) the pregnancy was interrupted. A resulting septic condition and the severity of the anemia required renewed blood transfusions. It was later found that the resulting hemolytic reactions resulted from the fact that the donors had been Rh positive, whereas the patient was Rh negative and moreover had Rh antibodies. The third patient, an Rh negative woman aged 31, had given birth to a child with erythroblastosis. Inadvertently the patient was given a transfusion of Rh positive blood, with fatal results.

Relation of Rh Factors to Abortions, Pregnancy Intoxications and Erythroblastoses.—Stadtmüller points out that abortions and stillbirths are frequently mentioned in the histories of families with erythroblastosis fetalis. He studied the Rh factor in women who had had repeated unexplained abortions or who had had pregnancy toxicoses. In 57 cases he was unable to corroborate the suspected causal connection. He thinks that for better clarification of the significance of the Rh factor it is advisable also to record negative observations.

Herpes Zoster Encephalitis.—Schmidt relates that a man aged 56, who had herpes zoster in the region supplied by the first branch of the trigeminus, died as a result of a simultaneously existing meningoencephalitis, which, however, had not been recognized. Drowsiness was one of the most noteworthy signs. In this respect the condition resembled Economo's lethargic encephalitis. The herpes zoster, like all other forms of virus encephalitis, is chiefly a polioencephalitis. The medulla and pons were most severely involved in the case under consideration. Further observations will be necessary to ascertain whether this localization of the inflammatory foci is typical for zoster encephalitis. The type of the microscopic changes is largely identical with those observed in other forms of virus encephalitis, particularly in those with epidemic encephalitis, except that the substantia nigra is less severely involved than in epidemic encephalitis.

Penicillin in Treatment of Peritonitis. J. Kweckel.—p. 1004.
Autochthonous Malaria in Region Formerly Free From It. G. D. Hemmes and A. Punt.—p. 1007.

A Blackwater Fever House.—Kho Lien Keng and Loe Ping Kian report a blackwater fever house in which 12 members of a family were continuously exposed to malaria during the three and one-half years of Japanese occupation. One year after the beginning of this exposure the first case of blackwater fever occurred. In all, 8 persons suffered from blackwater fever once or repeatedly. During twenty years preceding this period these people had lived in a quarter of the town where there was but little malaria. In those years they had fever attacks only rarely and never blackwater fever. Blackwater fever was also absent during two years after the family had left the severely infected neighborhood. There was a definite relationship between the outbreak of blackwater fever and the frequency of the malarial attacks. The use of quinine seemingly had no decisive influence on the development of blackwater fever.

Thyrotoxic Crises During Treatment with Antithyroid Substances.—Three cases are reported by ten Berg in which the symptoms of toxic diffuse goiter or of hyperthyroidism became more severe at the onset of treatment with thiourea and methylthiouracil respectively. In 1 of the 3 cases a veritable crisis developed. These cases differ from the hundreds of cases in which preoperative treatment with thiouracil never resulted in a postoperative crisis. The author thinks that the aforementioned cases can be explained by the theory advanced by Mahaux about spontaneous and postoperative hypothyroid crises. Strictly executed treatment with methylthiouracil reduces the thyroxine content of the blood greatly. After the operation there is a great need for thyroxine, which results in a greater production of the substance stimulating thyroxine and in a stimulation of the diencephalon. The author mentions

2 other cases in which crisis developed following strumectomy for which the patients had been prepared by methylthiouracil medication and in whom the basal metabolism had decreased to less than normal.

Encephalitis After German Measles.—Musaph reports that a man aged 24, after repeated attacks of tonsillitis, contracted rubella when an epidemic prevailed in the neighborhood. Three days after the development of the rash the patient became acutely ill with symptoms of encephalitis. Within thirteen hours after the onset the threatening encephalitis symptoms disappeared. Half a year after this illness only the abdominal reflexes in the middle and lower segment on both sides could not be elicited. Reviewing the French and German literature on encephalitis after rubella, the author found records of only 9 cases. Of 187 patients hospitalized with a diagnosis of encephalitis since January 1916 only the 1 described here had rubella as the underlying cause.

Normal and Pathologic Bone Growth in Light of Development of Cartilaginous Foci in Chondrodysplasia. A. Langenskiöld.—p. 367.

Choledochal Denervation in Biliary Dyskinesia.—Lagerlöf points out that in 1940 Reich suggested an operation to relieve the pain of biliary dyskinesia by sectioning nerves in the hepatoduodenal ligament. When patients with biliary dyskinesia following cholecystectomy and some patients with biliary colic in seemingly normal gallbladders were admitted to Lagerlöf's hospital, it was decided that Reich's operation might be justified in some who had daily or weekly attacks of biliary colic. Data are presented on 15 patients with dyskinesia following cholecystectomy who were subjected to choledochal denervation. The pain was relieved in 14 of these 15 patients. Simultaneous injections of morphine and secretin cause less pronounced rises of serum amylase and bilirubin following the choledochal denervation, which indicates that Oddi's sphincter contracted less strongly. Since the beneficial effect of the choledochal denervation as a rule did not last more than some weeks to months, it is probable that the nervous connections were restored. From a practical point of view it means that the operation is of little value and should be performed only when, on the suspicion of choledocholithiasis or pathologic process in the remnant of the cystic duct, the choledochus is explored and no pathologic changes are found.

Acute Interstitial Pancreatitis Caused by Hemolytic Streptococci in Foods.—Koller studied 2 patients with acute, interstitial, nonpurulent pancreatitis provoked by hemolytic streptococci and 1 patient with acute enterocolitis with a raised antistreptolysin titer. It appears that all 3 patients were members of the same household and had eaten of the same infected fish. The 2 patients with the pancreatitis died. The pathologic picture was identical with that of Zoepfel's pancreatitis edematosa and Elman's acute interstitial pancreatitis. The author stresses the need for careful bacteriologic examinations and recommends examination of the patient's feces and blood as a routine measure, as well as the determination of the antistreptolysin content of the blood. Positive bacteriologic findings should be an indication for chemotherapy.

Results of Treatment of Carcinoma of Corpus Uteri in Woman's Clinic in Helsinki During Years from 1931 to 1946. V. Turtola.—p. 47.
Subcutaneous Injuries of Pancreas. V. Taivainen.—p. 63.

Glomus Tumors.—Löfgren says that, although the literature on glomus tumors has somewhat increased, this type of tumor is not sufficiently known. The earlier literature had applied various terms to the tumor, but Masson in 1924 showed that it arises from the "neuromyoarterial glomera"; hence the term glomus tumor. Reviews of cases collected from the literature indicate that the sex distribution is about equal. Localization under the nail and other digital locations is seen almost exclusively in female patients, whereas localization to other parts of the extremities is more usual in males. Glomus tumors occur in patients of all ages and usually appear singly. They develop slowly and are rarely larger than a pea. They are mostly small, bluish, elastic, extremely tender tumors. The slightest pressure from clothing may cause intense pain. Surgery is the only effective treatment. The author reports 3 cases of glomus tumor, in 2 of which the tumor was located on the lip; in the third it was on the finger.

Scarification Treatment. G. Biörck, O. Göhle and C. Westman.—p. 739.
Ileus in Pregnancy. E. von Post.—p. 744.
*Cramps and Restless Legs in Acute Poliomyelitis. R. Luft and Ragnar Müller.—p. 748.

Cramps and Restless Legs in Acute Poliomyelitis.—Luft and Müller state that cramps in acute poliomyelitis seem not to have been previously reported in the literature. Of 32 patients (22 observed for one to two years, 10 for ten to twelve years) 15 had cramps localized in muscles affected during the acute stage of the disease. The occurrence of the cramps does not seem to depend on the degree of injury of the peripheral motor neuron. There is no relationship between the degree of paresis and the frequency and intensity of the cramps, which in most of the cases reported were constant during the time of observation. When cramps are especially troublesome, quinine gives good results. Of 18 patients in whom one or both legs were affected during the acute stage 3 (2 observed for ten years, 1 for one year) had restless legs with paresthesia usually in the lower part of the leg, sometimes in the thigh. Restless legs are ascribed to a vasomotor disorder.

Book Notices

War Stress and Neurotic Illness. By Abram Kardiner, M.D., Assistant Clinical Professor of Psychiatry, Columbia University, New York City. With the collaboration of Herbert Spiegel, M.D. Second edition of The Traumatic Neuroses of War. Cloth. Price, $4.50. Pp. 428. Paul B. Hoeber, Inc., 49 E. 33d St., New York 16, 1947.

This book is a restatement of Kardiner's earlier contribution to the study of traumatic neuroses originally entitled "The Traumatic Neuroses of War." The present edition contains an additional section concerning the acute phase of the war neuroses, written in collaboration with Herbert Spiegel. This section is an adequate, if incomplete, description of the emotional setting and of the psychologic and morale factors significant in the development of the war neuroses. There is no particularly new systematic approach in this part of the book; but, since it is based on the writer's own experiences in battle, it produces an authentic and vivid impact on the reader

The greater part of the book is devoted to the study of the chronic phase of the war neuroses. Kardiner makes much of the difference between the acute and the chronic phases. He adopts the rather unusual position that the acute phase of the illness can be understood only in the light of a thoroughgoing study of the chronic phase seen years after the onset of the illness. This is a rather unique criterion for the intelligible study of the disease process. The matter is usually considered to be quite the reverse. However, Kardiner has some notable contributions to make on the subject of psychopathology which he has elicited from the analysis of the chronic traumatic neuroses. His conceptual system is too unusual to be discussed briefly here. He prefers to substitute for the usual concepts of instinct and drive the "operation" concept of "action systems."

The action system concept represents a definite theoretical advantage from the point of view of studying the integrative mechanisms of the ego. However, the discussion is marred by Kardiner's insistence on a fundamental distinction between the traumatic neuroses and the transference neuroses. Such a sharp distinction cannot be maintained either on theoretical grounds or on the basis of Kardiner's actual clinical data. The effort to cling to this distinction gives the whole work a contentious, doctrinaire aspect which undermines the real value of the basic contribution. The work should actually be studied from the point of view of the application of the novel concepts set forth to our understanding of both the transference aspects and the traumatic aspects of all neuroses. From this point of view the book has great value in spite of its singular narrowness and incompleteness as a study of the neuroses of war.

Nutrition in Industry. International Labour Office, Studies and Reports, New Series No. 4. Boards. Price, $1.50; 6s. Pp 177, with illustrations. International Labour Office, Washington Branch, 734 Jackson Place, N.W., Washington 6, D. C., 3450 Drummond St., Montreal 25, 1946.

This is largely devoted to the activities and findings of government wartime feeding programs of Canada, the United States and Great Britain. The accounts reveal that industrial feeding programs, while not entirely new, were not adequate to meet properly the emergency occasioned by the war. One can say that each of the three governments found it necessary to overcome a weakness in national feeding. Consequently an international effort was made to influence the diets and eating habits of the vast numbers of workers required to produce the goods and munitions of war.

The publication contains a wealth of material on various governmental procedures, both general and special in nature, utilized in the three countries. It is enhanced with a number of photographs, charts and statistical data. Each of the three separate countries is given a definite section of the book. Part I is entitled "Nutrition in Canadian Industry," part II "The Wartime Food and Nutrition Program for Industrial Workers in the United States" and part III "Industrial Canteens in Great Britain." A brief introduction has been prepared by Dr. Frank G. Boudreau, executive director, Milbank Memorial Fund, chairman, Food and Nutrition Board, and chairman, Committee on the Nutrition of Industrial Workers of the National Research Council. A table of contents also forms a part of this publication. There is no complete index of the book.

Each of the three separate sections contains a brief outline in which the separate contributors not only sum up the results of the wartime feeding program but also speculate regarding the lasting benefits to be achieved as a result of communal feeding, which was so highly developed in the great wartime plants and factories. The general opinion seems to be that a peacetime nutrition program effectively performing the functions as indicated in this report could greatly improve the health of the workers. However, it is pointed out that besides efficiently operated installations there are other problems of a social and economic nature closely interwoven with the whole problem of nutrition which must be solved by the proper agencies before malnutrition will disappear as a problem of major international concern.

White Caps: The Story of Nursing. By Victor Robinson, M.D., Professor of History of Medecine, Temple University School of Medicine, Philadelphia. Cloth. Price, $3.75. Pp. 425, with 21 illustrations. J. B. Lippincott Co., 227 S. Sixth St., Philadelphia 5, 1946.

This history of nursing is written in such a manner that it immediately catches the reader's interest. The frailties of human nature are not glossed over. The good and the bad are recorded. The reader, however, emerges at the completion of the volume with a picture of the profession developed through an acquaintanceship with the personalities of a considerable number of the builders of the profession. The struggle to build this profession is described as long and hard and intimately tied up with the history of woman. The story of the development of modern nursing from its beginnings in the training school for nurses at Saint Thomas's Hospital in London is told in a colorful and lucid manner. Although at first this volume may appear too long and detailed for use as a textbook in nursing schools, the respect which it creates for a growing profession, and the devotion to the service of mankind which it so ably portrays, should commend it. The final section, entitled "March of the Nurses," provides a chronological table of events and biographies which serves to reemphasize and relate in concise form the main landmarks of nursing history.

Gynecology and Obstetrical Pathology with Clinical and Endocrine Relations. By Emil Novak, A.B., M.D., D.Sc., Associate in Gynecology, The Johns Hopkins Medical School, Baltimore. Second edition. Cloth. Price, $7.50. Pp. 570, with 512 illustrations. W. B. Saunders Co., W. Washington Square, Philadelphia 5, 1947.

The second edition of this excellent book is indeed welcome at this time. The introduction of the first edition provided students and practitioners with an authoritative textbook on gynecologic and obstetric pathology which has had wide acclaim. The author has worked and taught in this special field throughout his professional career. His wide experience and the abundance of material available in his laboratory are manifested in the contents of this volume. Furthermore, he has the rare ability of telling his story in simple, concise and clear language, which adds considerably to the value of this textbook. The present edition has more than a hundred new illustrations, many colored, which add much to the descriptions. The text and references have been brought up to date. This edition, like its predecessor, can be recommended to students and practitioners interested in gynecologic and obstetric pathology.

Dynamische Reaktionspathologie: Die Überwindung der medizinischen Grundlagenkrise durch die moderne Physik und Biologie, Entwicklung und Ziele einer eigengesetzlichen Medizin und ihre Auswirkung in Forschung, Praxis und Gesundheitspflege. Von K. v. Neergaard, Professor an der Universität Zürich, Zürich. Cloth. Price, 24 Swiss francs. Pp. 317, with 26 illustrations. Benno Schwabe & Co., Klosterberg 27, Basel 10, 1946.

"The real crisis is a struggle for a new conception of science." Medicine cannot stand on the basis of classic natural science any longer without becoming scholastic. Modern physics has fundamentally changed the old forms of thinking. Under the influence of classic science the conception of substance combined with the three dimensional conception of space leads to the question of the site of disease. Now we have a space-time unity, a four dimensional image of the world. According to the gestalt theory it is hopeless to try to understand the whole by way of the analysis of its elements. Physics and chemistry are sciences of the elements: the problem of biology is the whole system. Holism teaches that the processes of life cannot be understood from the mechanistic, physicochemical side, i. e. from the next lower phase. The whole is logically superior to its members.

Much more important than the morphologic form is the functional side, the dynamic equilibrium between the whole and its parts. Pathologic processes cannot be explained by disturbed normal physiology; something new occurs, the pathologic reaction. The readiness for a reaction is what matters most. The same factors may produce quite different pathologic conditions. These new facts cannot be understood from physiology or normal anatomy. This is decisive for the position of medicine as an independent field of research.

Modern milieu biology is interested in the active reaction to outside influences of the organism and does not see the organism as isolated from the milieu. It leads to medical sociology; a community is more than and quite different from a sum of individuals. Here too we see a gestalt-like structure. Diagnosis must be developed into a diagnosis of reactions. This is the basis of active treatment, which mobilizes the defensive powers of the organism. Healing is not directed to passive developments only but to active processes also. The laws of pathology are more general than those of physiology. This is expressed by the name "autonomic medicine." The understanding of the disease as a historical process is best expressed by the term "dynamic reaction pathology."

This is a summary and necessarily incomplete review of a book which is full of interesting ideas and stimulates the reader to think over the problems which medicine faces in our days. However, its somewhat alarming title is not fully justified. For decades we have heard about the "crisis" of modern medicine, and more than one book has been written in order to avoid or overcome it. In the meantime we have seen a progressive development in medical thought and practice, which can hardly be much promoted by programmatic declarations even though these are based on a profound knowledge of medicine, science and history such as the writer of this book possesses. In medicine more than in most other sciences progress can, at least to a great part, be measured by practical results.

Eye Surgery. By H. B. Stallard, M.B.E., M.D., F.R.C.S., Assistant Eye Surgeon, St. Bartholomew's Hospital, London. Cloth. Price, $11. Pp. 444, with 338 illustrations. William Wood & Co., Mt. Royal & Guilford Aves., Baltimore 2; John Wright & Sons, Ltd., 28 Orchard St., Bristol 1, England, 1946.

This book was written and illustrated by the author himself, without access to ophthalmic literature, while at sea, in military transports and in army camps. It is not a rehash of the often conflicting views of many authorities, but the reader is given the results of one man's observations and the methods he has used to cope with the many and manifold surgical problems presented by the eye and its adnexa. The author is a man of wide experience both in civil and in military fields, and his theories and results are related in this volume.

The introductory chapter contains useful instructions for the ophthalmic surgeon and his assistant and also deals with a description of layout and care of instruments, and preoperative and postoperative care of patients. A chapter on anesthesia and analgesia follows and then some 130 pages concerned mainly with plastic surgery of the eyelids. Reconstructive surgery for war injuries is covered in considerable detail. The remaining chapters of the book deal with the lacrimal apparatus, the extraocular muscles, the conjunctiva, cornea, anterior chamber and sclera, the iris, the lens, glaucoma, the retina, choroid and vitreous, traumatic surgery and the orbit. Each operation is preceded by a list of the instruments required and an account of the method employed for producing anesthesia or analgesia. This entails considerable repetition and contains only those operations which the author himself favors and practices. Some original matter consists of a description of the author's methods of extraction of intraocular foreign bodies by the posterior route, of implantation of radon seeds far back on the eye for intraocular neoplasm and his corneoscleral stitch in cataract operation. The chapter on the orbit contains much useful information, and an excellent description of a modified Kronlein operation.

The book is characterized by a lucidity of description, attention to detail and incorporation of valuable material not previously obtainable in book form. The reader, given reasonable experience in ophthalmic surgery, should be able to perform any of the operations described even if he has not had the opportunity to see them done by others. The work can be considered an authoritative English book on ophthalmic surgery and should be of considerable value to American ophthalmologists.

Pain in the Distribution-Area of the 4:th Lumbar Root: A Study of Pain Interpreted as Referred Pain and as Caused by Direct Irritation of the Nerve-Root. By Gösta von Reis. Acta psychiatrica et neurologica, Supplementum XXXVI. Paper. Pp. 135, with 30 illustrations. Stockholm, 1945

Pain within the area of the fourth lumbar root has been studied and interpreted partly as referred pain (in arthrosis deformans coxae) and partly as caused by direct disorder of the root (in disk herniation and osteoarthritic disorders in the spine). In 6 cases with pain similar to arthrosis deformans coxae the question of the cause of pain is undetermined.

Analyses of muscle tenderness, spontaneous pain and experimental irritation together with experimental anesthetizing of hip joints indicate that the pain in arthrosis deformans coxae can be interpreted as referred pain within, chiefly the area of the fourth lumbar root.

Rhizotomy of the fourth lumbar root in pain interpreted as referred pain within chiefly the distribution area of this root gave relief from pain in 12 of 14 cases. The pain is prone to recur. After an observation period of fourteen months there were satisfactory results in 6 of 14 operative cases.

Rhizotomy of the fourth lumbar root in cases with pain within the distribution area of this root gave, in 6 cases of pain of doubtful origin, freedom from pain in 4 cases during an observation period of respectively sixteen, twenty-two, twenty-four and twenty-four months. In a further case there was, after an observation period of twenty-three months, a result which was satisfactory from a practical point of view.

Section of the third and fourth lumbar sensory roots in conditions of pain caused by arthrosis deformans coxae resulted in a satisfactory condition in 9 of 18 operative cases after an observation period of nine months.

Sources of error in rhizotomy are discussed.

In about half of the number of cases with pain caused by arthrosis deformans coxae there existed a depression of the patellar reflex or the achilles reflex or both. Observations after sectioning the root speak in favor of the afferent impulses of the patellar reflex traveling via the third and fourth lumbar sensory roots. In about half of the cases conduction travels via the fourth lumbar sensory root alone.

After section of the fourth lumbar root, a diminution of the superficial sensitivity to pain is considered the rule (7 cases of 10). Section of the third and fourth lumbar sensory roots produced in all the cases (18) a diminution of the superficial sensitivity to pain.

The lumbar core dermatome of the superficial sensitivity to pain has been studied after eighteen sections of the fourth lumbar root. The area of diminution of the superficial sensitivity to pain has been considered characteristic of the core dermatome of the fourth lumbar root and has been compared with previously mentioned dermatomes associated with the fourth lumbar root.

A History of Nursing. By Gladys Sellew, Ph.D., R.N., Director, Department of Nursing, The College of St. Catherine, St. Paul, Minn., and C. J. Nuesse, Ph.D. Fabrikoid. Price, $3.75. Pp. 444 with illustrations. C. V. Mosby Co., 3207 Washington Blvd., St. Louis 3, 1946.

This textbook is a well organized and presented history of nursing. A sincere attempt has been made to correlate the development of nursing throughout the ages with the development of mankind and his consciousness of health and disease. Each chapter is carefully subtitled and is completed by study questions and a suggested reading list. The volume provides a considerable amount of medical and sociologic background related to each period of nursing history. The style and type of organization of the book are similar to those of many high school textbooks. However, there is a wealth of material which is readily available to the more mature student.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST

EFFECT OF AMPUTATION OF THE CERVIX ON CONDUCT OF LABOR

To the Editor:—Information is requested concerning the conduct of labor following Sturmdorf's operation on the cervix. Please cite data bearing on uterine rupture, premature delivery and the need for cesarean section, if any. M.D., Texas.

ANSWER.—Contrary to former ideas, Danforth has pointed out that the cervix is largely fibrous tissue containing few muscle cells. Partial removal of this structure need not interfere with the normal labor mechanism If a portion of the cervix remains and there is little scar tissue present the cervix may undergo normal effacement and dilatation. However, when the cervical amputation has been sufficiently complete so that no vaginal portion is present, labor is less likely to pursue a normal course. Furthermore, premature delivery is a fairly common occurrence following high cervical amputation.

The conduct of labor in a patient who has had an operation on the cervix should be conservative but the prognosis guarded. In the absence of any other contraindication to delivery through the pelvis the patient should be allowed to go into labor and the course followed intelligently. If effacement and dilatation proceed normally, delivery from below can be expected. On the other hand, if after a good test of labor the cervix fails to dilate normally, cesarean section should be considered. Previous plastic surgery for the correction of cystocele and rectocele in addition to cervical amputation should be considered sufficient indication for an elective cesarean section Spontaneous rupture of the uterus is a rare sequela following surgery of the cervix.

BLOOD SEDIMENTATION RATE IN SYPHILIS

To the Editor:—Will you kindly tell me the effect of syphilis in its different stages on the erythrocyte sedimentation rate? Victor F Woolf, M.D., New York.

ANSWER.—The erythrocyte sedimentation rate is a nonspecific reaction comparable to the body temperature and leukocyte count in that it gives information of a general character. In syphilis, as in certain other chronic infections, it is a gross measure of the extent and activity of the morbid process. The sedimentation rate may be increased in primary syphilis even before the blood serologic test becomes positive. The highest readings occur in association with florid secondary manifestations. In late syphilis erythrocyte sedimentation is rarely increased in the absence of overt clinical lesions. Following antisyphilitic therapy the sedimentation rate falls and is normal in patients who have been adequately treated.

The sedimentation rate does not have diagnostic value in syphilis except as it may call attention to a more or less occult clinical condition. In following the course of syphilitic infection and assessing the response to antisyphilitic therapy, the quantitative serologic test is a specific and far more reliable index of clinical activity.

PROTRUDED INTERVERTEBRAL DISK AND PREGNANCY

To the Editor:—A white woman aged 27 developed a severe unilateral sciatica after delivery of her second baby. This was believed due to a partially ruptured intervertebral disk and spontaneous recovery occurred about a year and a half after the delivery. What is the probability of recurrence of a similar episode with another pregnancy? What preventive measures might be taken? Herbert G. Barber, M.D., Sells, Ariz.

ANSWER.—If the labor was not extremely difficult and forceps were not used, the sciatica is probably the result of a partially ruptured intervertebral disk. If, in the future, labors are not difficult there is less probability of the recurrence of symptoms. One of the characteristics of protruded intervertebral disk is the intermittence of symptoms.

The preventive measures to be taken are (1) avoidance of stooping, lifting or straining, (2) wearing of a lumbosacral support and a good maternity corset during pregnancy and (3) removal of the disk.

EFFECT OF LOW TEMPERATURES ON REACTIONS OF BLOOD

To the Editor:—In view of the difficulty in heating our buildings, I have been concerned about certain reactions that have connected themselves in my mind with low temperatures. I should like to have an explanation and advice with reference to them. 1. The coagulation time of the blood is reported as 10 minutes by one laboratory and 20 minutes (at temperature at 11 C.) by another laboratory. The first laboratory insists that 10 minutes normal for the conditions of temperature under which the test was made. 2. Prolonged bleeding time has been observed in that bleeding did not cease from the lobe of the ear,where a prick had been made for hemoglobin estimation, for a period of fifteen minutes, which, in the instance in view, coincided with the time it took the patient to get to a properly warmed room. 3. When the blood was centrifuged with view to separating the serum for a Kahn test, the serum solidified. (The temperature was not freezing.) 4. In giving a transfusion in a room which was inadequately heated, the citrated blood clotted and could not be transfused. Was this due to suppressed chemical ionization and reaction with the sodium citrate? Can this be forestalled in the absence of heating facilities? 5. Can blood typing and blood matching under these conditions of temperature be considered reliable? 6. Are there changes in the composition of the blood of sufficient moment to account for any of the phenomena mentioned on the basis of the individuals concerned living in a constantly cold temperature? M.D., China.

ANSWER.—The inquiry regarding the effect of temperatures on coagulation of blood is most interesting. However, there is not enough information regarding the procedures that were followed. With the insufficient data specific conclusions cannot be ventured nor can anything but general advice be offered.

1. The coagulation time of blood is normally increased with temperature lower than that usually considered as normal room temperature. At a temperature of 11 C. the coagulation time determined by the Lee and White method could easily be as much as twenty minutes. It is assumed that a test tube method with properly cleaned glassware is the one under consideration. It would be advisable, if at all possible, to carry out coagulation tests in a water bath at 37 C. immediately after withdrawal of the blood and placing it in a tube which should be previously warmed to 37 C.

2. Bleeding time is prolonged in cold temperatures paralleling the coagulation time. If it is not possible to carry the test out in a warm room, the standard time should be determined under the conditions of the test.

3. Blood for a Kahn test should be given a preliminary prolonged centrifugation and then further centrifugation after separation of the clot from the side of the tube. In other words, all fibrin should be formed from the fibrinogen before an attempt is made to remove the serum. In fact, if the tubes were allowed to stand until the retraction of the clot is complete, the serum would be more suitable for serologic procedures.

4. The data given are insufficient to explain the clotting of the citrated blood. This should not occur if proper mixture with the anticoagulant is carried out.

5. Blood typing and blood mixing should be reliable under the conditions of temperature mentioned. In fact they may be more reliable than at higher temperatures. However, there may be considerable difficulty in misleading results due to "cold agglutinins." Here again it would be advisable to use some sort of water bath, maintained at 37 C., to clarify any confusion that might be caused by abnormal agglutinins.

6. It is not possible to answer this question. It could be a subject for real clinical investigation, but most careful controls would be required before any conclusions could be drawn.

SPONTANEOUS CURE OF SYPHILIS

To the Editor:—What percentage of people contracting syphilis become spontaneously cured without any treatment? Have there been any well controlled studies on this question? Dean C. Austin, M.D., Brookings, S. D.

ANSWER.—The only first class study which deals with the spontaneous curability of syphilis is that of Bruusgaard, E.: Ueber das Schicksal der nicht spezifisch behandelten Luetiker, *Arch. f. dermat. u. syph.* **157:**309, 1929. This article has been further analyzed from the biostatistical point of view by Sowder, W. T.: Interpretation of Bruusgaard's Paper on the Fate of Untreated Syphilis, *Am. J. Syph., Gonor. & Ven. Dis.* **24:**684 (Nov.) 1940. A still further discussion of the matter may be found in chapter III, on the prognosis of syphilis, in the monograph by Moore, J. E.: The Modern Treatment of Syphilis, ed. 2, Springfield, Ill., C. C Thomas.

The available evidence suggests that about 25 per cent of persons contracting syphilis become spontaneously cured without any treatment and that another 25 per cent achieve complete latency (though remaining seropositive in the blood), living to a ripe old age and dying of something else.

COURSE AND FUNCTIONS OF SYMPATHETIC NERVE FIBERS AROUND HEART AND LARGE BLOOD VESSELS

To the Editor:—I am a general practitioner with a country practice, and only a meager portion of the medical literature is available to me for reference. I have a particular reason for being interested in obtaining the best information available in regard to any autonomic supply that might originate from the aortic plexus and/or the cardiac plexus and accompany the innominate, the left common carotid and left subclavian arteries as they leave the aorta. I think it is established that both vertebral arteries have a large autonomic accompaniment the origin of which is from the lower cervical and upper thoracic sympathetic ganglions, and of course the carotids high in the neck are joined by, and accompanied upward, by a large autonomic supply from the superior cervical ganglions. The thought has occurred to me that autonomic fibers from the larger plexuses of the aorta and possibly of the heart might accompany the vessels first mentioned at their origin from the aorta. I have tried to ascertain the truth or fallacy of this deduction by referring to the literature available to me without success.

D. C. Simmons, M.D., Kilgore, Texas.

Answer.—All the great vessels arising from the aortic arch are accompanied with vasomotor fibers of the sympathetic component of the autonomic nervous system. Such fibers form plexuses which invest the subclavian, carotid, vertebral and internal mammary arteries as well as the thyrocervical and the costocervical trunks.

Functionally these periarterial plexuses are primarily concerned with control of vascular tonus and therefore of the diameter of major arteries and their branches. Some fibers innervate glands and smooth muscle in the skin. The subclavian plexus of sympathetic fibers, for instance, continues along the axillary and brachial arteries and through their terminal branches may extend to the skin of the superior extremity (to arrector pili muscles and to sweat glands). The sympathetic fibers accompanying the thyrocervical trunk extend to the thyroid gland along the inferior thyroid artery.

Most of the sympathetic fibers that form the periarterial plexuses in question are of the postganglionic, unmyelinated type. They originate mainly in the inferior cervical ganglion or, if the latter is fused with the first thoracic sympathetic ganglion, in the stellate ganglion.

There is no evidence that any of these plexuses are functionally dependent on the cardiac or on the aortic plexus of thoracic levels. The two cardiac plexuses (superficial and deep) are terminal for the heart and the lungs through their extensions along the coronary and the pulmonary arteries. The periaortic plexus in the thorax is less extensive than that of the abdominal aorta. There are no large, unpaired visceral arteries coming off the thoracic descending aorta. The visceral outflow of the thoracic sympathetic trunks, therefore, streams less into a thoracic periaortic plexus than into the splanchnic nerves that pierce the diaphragm and supply the celiac plexus.

Vasomotor fibers of the periarterial plexuses (subclavian, internal mammary and so on) are by no means the sole source of sympathetic innervation of the superior extremity or of thoracic skin. Many postganglionic, unmyelinated fibers reach these regions through gray communicating rami from the lower cervical and upper thoracic sympathetic trunks. These gray rami connect the sympathetic trunks with the roots of the brachial plexus and with thoracic spinal (intercostal) nerves. A great deal of visceral efferent, sympathetic outflow, therefore, occurs through the respective spinal nerves by an admixture of unmyelinated fibers. They follow mainly the distribution of sensory nerves and thereby reach the vessels of the subcutis and the skin. There is evidence that recovery from fatigue of striated muscle is also influenced by sympathetic stimuli.

Some reports indicate that periarterial sympathectomy produces only temporary vascular symptoms followed by normal vascular tonus. The dual course and supply of sympathetic fibers to the arm would explain such results.

THE ODOR FROM ILEOSTOMIES

To the Editor:—A patient of mine who carries a permanent ileostomy complains of persistent and disagreeable odors. Is there any medication that would help me eliminate this condition?

Charles M. Robbins, M.D., Newark, N. J.

Answer.—Many patients complain a great deal about the malodor from colostomies and ileostomies. The administration of charcoal frequently is sufficient to decrease the odor. This acts simply as an absorbent and should be administered in doses sufficient to control the odor. Another substance which is of value is kerol 3 minims (0.18 cc.) administered in a capsule once daily before breakfast.

PAIN IN RIGHT UPPER ARM

To the Editor:—Information is requested to assist in alleviating pain located deep in the right upper arm at the level of the insertion of the deltoid muscle. The patient is a white woman aged 27 with a history of direct trauma to the right arm three years ago. There have been intermittent deep seated pains lasting a day or two during this time. Since December 1946, however, the pain has been almost constant and aggravated by motion. X-rays of the shoulder, humerus and elbow are completely normal. Diathermy, infra-red and other methods of physical therapy such as massage have likewise been of no help. Moderately large doses of B complex were administered parenterally without effect. Aspirin compound with and without codeine have not eased the distress. The patient states that the pain feels as though it was within the bone itself. I have felt that this was largely a psychosomatic problem but I am writing to see if this may not represent some syndrome.

M.D., Connecticut.

Answer.—This patient probably has one of four conditions: (1) calcified deltoid bursa, (2) neuritis of the axillary nerve, (3) brachial neuritis, (4) functional nervous disorder. It is suggested that a complete neurologic examination be made to rule out these conditions. If objective evidence of organic disease is not found the patient should have a psychiatric examination.

DETERMINATION OF PROTHROMBIN TIME

To the Editor:—Has any work been done on the duration of prothrombin time studies on plasma? That is, for how long a time can plasma prothrombin time studies be delayed and yet be reliable? Will plasma prothrombin time be reliable if done after one or two days from the time of the drawing of the plasma?

Harry W. Orris, M.D., Bronx, N. Y.

Answer.—For an accurate determination of prothrombin time, the test should be done within three or four hours after the blood is drawn. In twenty-four hours the prothrombin activity is often reduced 50 per cent even when the blood is stored in a refrigerator. The loss of prothrombin activity according to A. J. Quick (On the Constitution of Prothrombin, *Am. J. Physiol.* **140**:212 [Nov.] 1943) is due to a destruction of component A of prothrombin by oxidation. This can be minimized by keeping the blood cold and covering it with a layer of liquid petrolatum.

ANORCHIDISM

To the Editor:—While operating for a right undescended testis, I was unable to find either the testis or any of its appendages. The retroperitoneal area up to the kidney and medially into the rectovesical septum was explored without finding any testis. There was no evidence of any spermatic vessels. Is it possible that the patient was born with only one testis, the left, which was of a size greater than would be expected in a 13 year old boy? Or was the testis present but in some ectopic position eluding exposure?

M.D., New York.

Answer.—From the evidence submitted it would appear the patient has only one testis. This is especially likely since the retroperitoneal area up to the kidney and medially into the rectovesical septum was explored. This condition is known as anorchidism, which at one time was considered rare but which recent observations prove to be not infrequent.

TENDENCY TO CONGENITAL MALFORMATIONS

To the Editor:—A married woman aged 26 was recently delivered of her second child within a fourteen months period. Each infant lived approximately thirty-six hours and died of a congenital heart defect (proved by necropsy). The first pregnancy was accompanied with a moderate amount of nausea and vomiting, the second with much less. Each pregnancy was essentially normal, although each child was carried beyond the estimated date of delivery (one month and two weeks respectively). All laboratory studies were normal (blood count, urinalysis), blood Wassermann negative and Rh factor positive. The patient took antepartum medication of small doses of thyroid, iron, calcium and vitamin D. The questions brought up by the patient are what are the chances of having a normal baby? Can there be any kind of chemical or other incompatibility between the tissues of the wife and the tissues of the husband, and if so, how can it be determined? The family history is negative for any kind of abnormality on either side. The patient will soon try a third pregnancy unless a definite contraindication or likelihood of a poor prognosis exists.

M.D., Pennsylvania.

Answer.—Statistically there is an increased hazard for a patient like this to give birth to another baby with some gross malformation. However, the hazard is not sufficiently great to advise against future pregnancies. It is entirely possible that future children will be normal.

There is no scientific evidence that chemical or other incompatibilities between husband and wife exist.

IDIOSYNCRASY TO DRUGS

Chairman's Address

CARL A. DRAGSTEDT, M.D., Ph.D.
Chicago

In 1822 Paris[1] wrote as follows:

> *Constitutional peculiarities, or idiosyncrasies, will sometimes* render the operation of the mildest medicine poisonous. . . . I have seen a general erysipelas follow the application of a blister, and tormina of the bowels, no less severe than those produced by the ingestion of arsenic, attend the operation of purgatives composed of senna. In some constitutions antimony has been known to produce a ptyalism; Dr. James assured Sir George Baker that he knew 6 instances of it, although the patients thus affected had neither their teeth loosened nor their breath made offensive. The peculiar susceptibility of certain individuals to the effects of particular plants is also very singular. Murray relates that unpleasant symptoms have been experienced by merely keeping aconite for some times in the hand, or on the bosom. I am acquainted with 2 persons in whom the odour of Ipecacuan always produces a most distressing dyspnea: there are some idiosyncrasies so singular and incredible, that nothing but unimpeachable testimony could sanction our belief in their existence.

In 1843 Pereira[2] wrote as follows:

> Idiosyncrasy. Under this denomination are included these peculiarities which affect the functions of organs, without having any obvious relation to development, and which are not common to a number of individuals. Its effect in modifying the effects of medicines is, in general, to increase their activity. Thus, some individuals are peculiarly susceptible to the action of opium, some of mercury, and others of alcohol. The odour of ipecacuanha will, in certain persons, produce short and difficult respiration, approaching almost to a paroxysm of asthma. The late Mr. Haden has related a case in which two drachms and a-half of Tincture of Colchicum produced death: the mother of the patient was also exceedingly susceptible of the action of colchicum even in small doses. In some instances the effect of idiosyncrasy is to diminish the activity of the medicines. Thus some persons are exceedingly insusceptible of the action of mercury.

It is clear that the early writers used the term idiosyncrasy to imply an abnormal response to drugs and that they recognized that this abnormality could be either quantitative or qualitative. While a quantitative variability in susceptibility to drugs has had casual recognition for centuries, it received little serious study until the last two decades. Recent studies have shown that when due account is taken of all the tangible factors, such as age and weight, which might alter the susceptibility to drugs, there still remains a characteristic and rather wide normal variability in the quantitative response to drugs. Pharmacologists now take cognizance of this by the use of such terms as ED_{50}, ED_{99} and ED_1, signifying by the first the average dose of a drug which is effective in 50 per cent of the population and using the latter two terms to give expression to the range of variability by indicating the doses which are correspondingly effective in 99 per cent and 1 per cent of the population. Where the data are available, such figures would give expression to the normal range of quantitative variability and one should require variations beyond these extremes before calling them abnormal. Persons showing susceptibilities at or beyond these extremes could be called tolerant on the one hand and hypersensitive on the other, and it would seem wise to strive for precision of meaning by using the term hypersensitiveness only in the quantitative sense. The quantitative variability in the response to drugs was the subject[3] of the Chairman's Address in 1939 and will not be dealt with further here, except to say that it has not been particularly disturbing in clinical practice and, as far as I am aware, has seldom precluded the use of any drug. Largely because of this fact, the term idiosyncrasy has come to have the narrower meaning of a qualitative abnormality in the response to drugs, signifying such effects as urticaria, neuritis, jaundice, anemia, leukopenia and the like, which some drugs produce in some persons but do not produce in the majority, irrespective of the dose employed. In the very definition of idiosyncrasy, then, physicians are confronted with two aspects of the problem: what persons? and what drugs? With respect to the former, practitioners today do not appear to know much more than did their prototypes of one hundred years ago. Whether idiosyncrasy is due to a constitutional defect, unchangeable and incurable, or to a transitory state brought about by disease or nutritional deficiency is not understood. The statement is commonly made that some 10 per cent of the population have an inherited predisposition to the allergic diseases caused by foods, inhalants and similar environmental agents. Is this the same fraction of the population that shows idiosyncrasy to drugs? This question should have a decisive answer, but I can find little beyond scattered reports of idiosyncrasy to drugs observed in persons with or without history of allergy in self or family on which to base a definitive answer to this question. Furthermore, even if the answer to this question were in the affirmative, it would not have advanced the understanding of the fundamental nature of this constitutional element to any notable extent, because there is no satisfactory explanation as to why some people become allergic and others do not. The possible kinship of drug idiosyn-

crasy to allergy, alluded to by this question, will be dealt with later.

With respect to the question, What drugs? investigators are about equally embarrassed for an answer. Experience has taught that idiosyncrasies to acetylsalicylic acid, aminopyrine, the organic arsenicals, the sulfonamide drugs, thiouracil, quinine and several others are considerably more frequent than those to alcohol, amphetamine, cascara sagrada, chloral hydrate, digitalis and the like, but there is little ground for any generalization that would have prophetic value as to the potentiality of idiosyncrasy for a hitherto unknown drug. It was for a time considered that aniline derivatives had a special predilection to idiosyncrasy, but I know of no substantial evidence to support this assumption, and the rather striking propensity for thiouracil and other nonaniline compounds to offend in this respect seems good reason to view it as inadequate. On the basis of the studies by Obermayer and Pick,[4] Wolff-Eisner,[5] Landsteiner and Chase[6] and others, it seems clear that certain drugs, by combining with body proteins to form antigenic conjugates to which the body may then become anaphylactically reactive, produce their untoward effect by this immunologic mechanism. But in many instances the occurrence of an idiosyncrasy to a drug is the only evidence one has that such an antigenic conjugate exists or can be produced, and there is no laboratory method by which this can be determined with certainty. Just as the physical examination of a patient usually fails to reveal anything informative as to the risk of idiosyncrasy on the part of a particular patient, so does the chemical examination of a drug usually fail to inform the physician of the potentiality that it may have. A representative of one of the drug firms told me, half in jest but half in earnest, that he was about ready to conclude that the most economical procedure with respect to a new drug would be to determine whether a large number of people could take it without untoward reactions before spending a lot of money in the laboratory and clinic to determine what it might do.

Consider the course of events attending the advent of a new drug. It is synthesized by the chemists. It undergoes various screening tests as to its actions and effects by the pharmacologists. Its toxicity is surveyed in some laboratory animals. It is distributed for controlled clinical investigation. It shows some therapeutic merit. It is released for general therapeutic trial and then—usually within three or four months—reports describing its unexpected and untoward reactions begin to appear. Was this not the story with dinitrophenol, the various sulfonamide compounds, penicillin, thiouracil, trimethadione ("tridione" N. N. R.) and many others? Meanwhile a furor of anxiety and expense ensues. The pharmaceutic manufacturer is called on to check and recheck the lot of drug with which the incident occurred to verify it as an idiosyncrasy rather than an accident, the physician has qualms as to his liability and the patient is distressed, if for no other reason than to learn that he is abnormal. This is obviously an unsatisfactory state of affairs begging for a solution. The medical profession has largely abandoned such drugs as dinitrophenol, aminopyrine and cinchophen in cases in which the therapeutic need does not warrant the therapeutic risk and has had its use of many other drugs definitely circumscribed.

To consider in more detail the character of idiosyncrasies, in the first place it should be agreed that some of the untoward or toxic manifestations that may attend the administration of a drug should not be considered as idiosyncrasies at all. For example, the urinary suppression that may occur with some of the sulfonamide drugs, and which is accounted for by their excretion and precipitation in the urine, is undoubtedly a toxic phenomenon which could be produced regularly if the proper precautions were not taken. The prothrombinopenia and hemorrhagic tendency which large doses of salicylate compounds may produce is another example of a normal toxic response that should not be called idiosyncrasy, even though it does not occur in every case in which the drug is administered. Secondly, it seems indisputable that there are a number of reactions to drugs which meet the various criteria characteristic of allergic reactions. Bronfenbrenner,[7] in a scholarly analysis of this problem, stated:

> These and other similar findings supply important evidence in favor of the view that the contact dermatitis type of response to nonantigenic substances need not be considered as a phenomenon apart from ordinary allergy. . . . Whatever the actual mechanism responsible for the sensitization with initially nonantigenic substances may be, it appears that, in the final analysis, in human beings as well as in animals the retention of chemicals in the tissues for a more or less prolonged period, as in the case of intracutaneous introduction, increases the likelihood of sensitization. Apparently local irritation with the following inflammatory tissue changes facilitates the formation of conjugates.

The untoward reactions to acetylsalicylic acid appear to be allergic in all instances, and a substantial number of the sulfonamide and penicillin reactions appear to be on an allergic basis. Thirdly, there are other types of idiosyncrasy in which the weight of evidence indicates that the reaction is not of an allergic nature. In a comprehensive review and analysis of the cases of jaundice, with or without acute yellow atrophy of the liver, attributed to various drugs, Ottenberg and Spiegel[8] concluded that the strict criteria of allergic sensitization were not satisfied. Also, a recent editorial[9] in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION summarizes the evidence incriminating cinchophen as an offending agent in this regard by concluding that the relationship of this drug to this condition is unproved and suggesting that the existence of an infectious hepatitis may well account for many of the reported incidents. To take some other examples, it has recently been shown[10] that dinitrophenol regularly produces cataracts in chickens and ducks, so that in these animals this reaction is a normal one and not entitled to the designation of idiosyncrasy. It seems highly probable from these observations that this toxic reaction is conditioned by the presence or absence of some factor which is usual in these animals but unusual in man. In this instance one has little hint as to what the conditioning factor may be. For other cases there are some hints. Succinyl sulfathiazole uniformly produces a granulocytopenia and anemia in rats.[11] This appears to be due to its inhibition of the intestinal bacteria which synthesize folic acid and thus indirectly to a folic acid deficiency, because the administration of adequate amounts of folic acid prevents the effect.[12] There is the suggestion from these observations that some of the drugs which produce granulocytopenia in man may do so by related mechanisms. I say this in spite of the fact that there are some disturbing observations difficult to harmonize with this concept. For example, Heilig and Visveswar[13] have reported the successful treatment of 2 cases of malignant leukopenia with sulfapyridine, which according to such a concept would be expected to intensify the process. Also, Newman and Jones[14] have reported that the prophylactic administration of folic acid in man failed to prevent an agranulocytosis by thiouracil. The observation[15] that ascorbic acid reduces the number of untoward reactions experienced with neoarsphenamine and oxophenarsine hydrochloride ("mapharsen" N. N. R.) suggests that most of these reactions are not of an allergic nature, because the best explanation for the action of ascorbic acid in this connection is that it reduces or prevents the oxidation of these compounds to toxic breakdown products. This also appears to be true for other organic acids.[16] Müller[17] has suggested that some cases of polyneuritis due to sulfonamide compounds may result from a purely toxic damage to the nerve tissues in the presence of predisposing factors such as achylia, thiamine deficiency or previous damage to the nervous system; Jorgensen and With[18] have reported some cases in which the disorder of pyrrole metabolism known as porphyria appears to have been the conditioning factor for untoward reactions to barbiturates. There is substantial reason to conclude, therefore, that a variety of drug idiosyncrasies may depend on various nonallergic factors, and it seems probable that some drugs may produce both allergic and nonallergic types of toxic reactions at the same time. There would seem to be some merit in an attempt to distinguish between these reactions, and to that end I would suggest the following provisional criteria:

1. An allergic basis seems to be indicated when the pattern of the toxic reaction is consistent with that of the allergic disorders produced by antigenic agents. This means that reactions characterized by urticaria, dermatitis, angioneurotic edema and asthma are probably allergic in character; that reactions characterized by jaundice, acute yellow atrophy of the liver and optic atrophy are probably not allergic, while granulocytopenia, anemia, thrombocytopenia and polyneuritis may well be one or the other.

2. An allergic basis seems to be indicated when a priming or sensitizing administration of the drug appears to be a factor in the history, while a nonallergic basis seems to be indicated when either long-continued administration or the use of substantial doses appears of major importance.

3. An allergic basis seems to be indicated when the untoward reactions are alleviated by epinephrine, diphenhydramine hydrochloride ("benadryl hydrochloride" N. N. R.) and similar agents, whose ameliorating effects are most reasonably interpreted on the basis of an antiallergic effect. A nonallergic basis seems to be indicated for those reactions which are alleviated by ascorbic acid, folic acid, thiamine and other agents whose ameliorating effect is not reasonably credited to an antiallergic effect.

As indicated, this outline of criteria for differentiating the allergic from the nonallergic reactions is only an improvisation which requires further study and amendment. But even when perfected such a classifying of reactions would become only an exercise in semantics unless it pointed the way to a solution of the two important aspects of this problem of idiosyncrasy, namely, the ability to forecast the likelihood of idiosyncrasy on the part of a given drug and the ability to control or treat the reactions that occur. With respect to the latter it seems clear that the general methods of preventing and treating allergic reactions would be different from those appropriate to the nonallergic responses. With respect to the former there are hints in the literature—and as yet they can be called little more than hints—that the propensity of a drug to produce untoward reactions in man might be determined by a more exacting study of its effects in experimental animals. Prolonged administration to monkeys might disclose a drug's tendency to produce optic atrophy;[19] administration to chickens, its tendency to produce peripheral neuritis[20] or cataracts;[19] administration to rats, its tendency to produce granulocytopenia,[11] and the appropriate administration to guinea pigs and rabbits, its tendency to provoke a dermatitis.[21] Perhaps with the aid of a complete menagerie the physician might learn to foretell all the possibilities.

I began this paper with some references to what was known about idiosyncrasy one hundred years ago. At this Centennial Celebration the members of the medical profession have been congratulating themselves with reviews and résumés of the marvelous accomplishments of this past century, but it is obvious from what has been said as to the tenuous nature of the current understanding of idiosyncrasies that this is one problem that has challenged physicians seriously and thwarted them shamefully. The reason for failure seems to me to have been indifference and neglect at coming to grips with the problem, largely because all have been buoyed with the hope that they could learn to evade it. The chemists have been seen to synthesize sulfonamide compounds that will do what sulfapyridine will do but with less risk of untoward reactions, to synthesize propyl thiouracil that will do what thiouracil does but with less risk, and so on, and it is somehow felt that the inex-

haustible legerdemain of the chemist will provide substitute compounds that never show any idiosyncrasy. The physician beseeches the chemist as follows:

> Build me newer molecules,
> O my Soul—
> As the swift seasons roll
> Let each new compound,
> Safer than the last,
> Avoid the reactions observed in the past
> Till all at length are free
> From vexing idiosyncrasy.

But I do not believe that medical practitioners can take pride in evasion as the answer to the problem, nor am I optimistic enough to belive that it will ever be possible to evade the issue completely. To me it represents one of the most challenging problems in medicinal therapeutics.

THE OBSTRUCTIVE PROSTATE

FRANK HINMAN, M.D.
San Francisco

The prostate lies at the neck of the bladder between the two sphincters surrounding the urethra from which it originates. The forty-odd ducts of this tubuloalveolar structure open onto the lateral and posterior walls of the urethra. The glands and ducts are embedded in an extensive framework of fibrous and smooth muscle, the whole enclosed in a common fibrous capsule penetrated by the ejaculatory ducts, which open on the verumontanum at about the middle of the prostatic urethra posteriorly. Normally, there is no lobulation. Le Duc's[1] careful study, by the injection of individual ducts with India ink and the demonstration of the distribution of each unit later after the specimen had been made translucent, disclose lateral and median portions only, no separate anterior or posterior lobes.

The only function of the prostate is to aid in reproduction. It forms no internal secretion and its external one, as Huggins[2] and others concluded after extensive studies, serves no greater purpose. It is an accessory in function, along with the seminal vesicles and the bulbourethral glands of Cowper, but because of its position at the neck of the bladder and the peculiarities of its changes with age it takes the lead over all in morbidity.

The obstructive prostate is of several varieties. Benign enlargements and median bar formations are almost always obstructive; inflammations, cysts, prostatic calculi, leiomyomas and fibromyomas occasionally, but cancer infrequently, unless associated with one or more of the preceding conditions. Benign enlargement and carcinoma are common affections, each with a high rate of disability and death. Since obstructive conditions are so frequently associated with carcinoma and time will not permit full presentation of all of them, the discussion will be limited to benign enlargement and carcinoma.

Benign enlargement of the prostate is not a hypertrophy or merely a hyperplasia of the prostatic elements, the terms commonly used. The majority of authorities believe that it is a new growth of fibrous, muscular and glandular tissues, serving no physiologic purpose, a fibromyoadenoma. It occurs uniformly as spheroids or lobules about that portion of the urethra above the level of the verumontanum. It is never found distal to this structure except by encroachment from size. It is not invasive but always encapsulated, and with growth it compresses the uninvolved parenchyma of the prostate into the so-called false capsule from which it can be enucleated en masse. It can take the form of lateral, median, commissural, subcervical, subtrigonal or anterior lobulation alone or occur in various combinations of these, the most frequent being bilateral and median lobular enlargement. It is periurethral and as it gets bigger and bigger enlarges downward, the urethral type; upward, the vesical type, invariably within the internal sphincter; or, as is usual, both ways.

Here then is a new growth whose regular rel ship to neighboring structures indicates a commo origin. The constant effect denotes a constant ant cedent. What is it? Jores[3] in 1894 was probably th first to distinguish periurethral from true prostati glands (fig. 1) and, by tracing the ducts through serial sections, had shown how several early enlargements seemed to involve these periurethral glands and not the true prostatic tissue. Following this lead, Motz and Perearneau[4] (1905) attempted to show that enlargements arise from these "glandes periurethrales

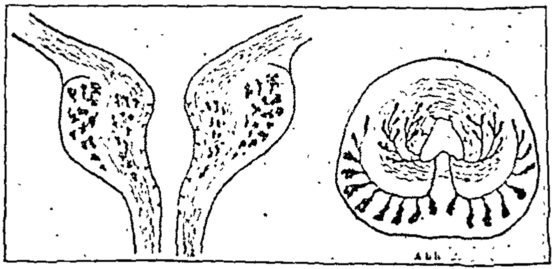

Fig. 1.—Diagrammatic representation of the true prostatic glands the periurethral glands. (From Adrion, W.: Ein Beitrag zur Aetiolog der Prostatahypertrophie, *Beitr. z. path. Anat. u. z. allgem. Path.* 191-202, 1922.)

Reischauer[5] in 1925 offered the first plausible ex nation of how this occurs, and his theory has been supported by Grassman[6] (1928), Obendorfer (1931), Deming and others[8] (1935), Le Duc[1] (1939) and others.

Reischauer assumed that the initial lesion is fibrous or fibromyomatous nodule which extremely early and rapid penetration of glandu elements from the periphery (fig. 2). The pr begins in the submucosa of the prostatic urethra an vesical neck as multiple outshoots of young spindl cells, which soon develop into small fibromas ar fibromyomas which are quickly invaded by th ingrowth of the adjacent glandular tissue to form th pathologic picture of fibromyoadenomas, the benig enlargements of the prostate (figs. 3 and 4). Appar ently glandular masses are never found witho

aglandular areas, although Deming and Neumann[9] found 6 aglandular masses without glandular invasion in the 24 prostates studied. No one has ever demonstrated this process of new growth in the prostate proper although leiomyomas and fibromyomas are found there occasionally.

One may perceive from the preceding facts what the prostate is and how it forms and will want to know, I am sure, why more than 50 per cent of men over 45 years of age develop benign enlargement of the prostate. Unfortunately no one knows why, but most investigators suspect some sort of endocrine disturbance as the fundament. Deming thinks the prostate of dogs and other mammals is probably Mullerian in origin and suspects the periurethral glands of man of being so too. This might explain why the diffuse enlargement in dogs is different from the lobulated enlargement found in man. Monkeys also develop diffuse enlargement. They have no periurethral glands. No one, *however, has demonstrated the embryologic origin of* these glands. Johnson's[10] careful study in 1920 demonstrated neither submucosal nor mucosal glands.

There are more than a dozen other theories, the most popular probably being that it is not a new growth but an inflammatory reaction, and Wade[11] (1914), with this in mind, proposed the term "chronic lobular prostatitis." The lesion microscopically is something like chronic mastitis or cystic hyperplasia of the breast, the analogue of endometrial hyperplasia in the uterus, both of which are forms of abnormal involution. This similarity and its incidence in later life, when disturbance of this kind occurs, give additional support to an endocrine factor as the cause. When this is known there may be found a means of correction, and then there will be a gradual decline in the progressive successful surgical therapy which has reduced the earlier woeful morbidity of this disease to a remarkable minimum in recent years.

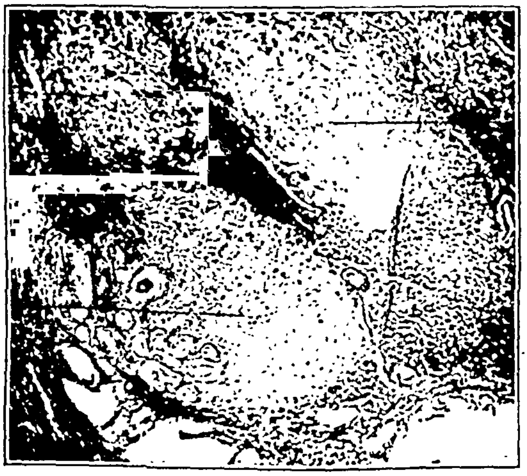

Fig. 2.—Microscopic demonstration of the invasion of fibromyomatous tissue by adjacent glandular tissue as the initial lesion in benign prostatic enlargement (from Reischauer[2]).

Cancer of the prostate, like enlargement, occurs in later life and the two often occur together but are unrelated otherwise. Unlike enlargement, which involves periurethral glands, cancer arises from any other part of the parenchyma of the true prostate, usually in the periphery. It is this external position which makes the early recognition of its presence possible. When it arises in portions beyond reach of the examining finger it becomes an occult form of the disease, a form which gains importance with attention.

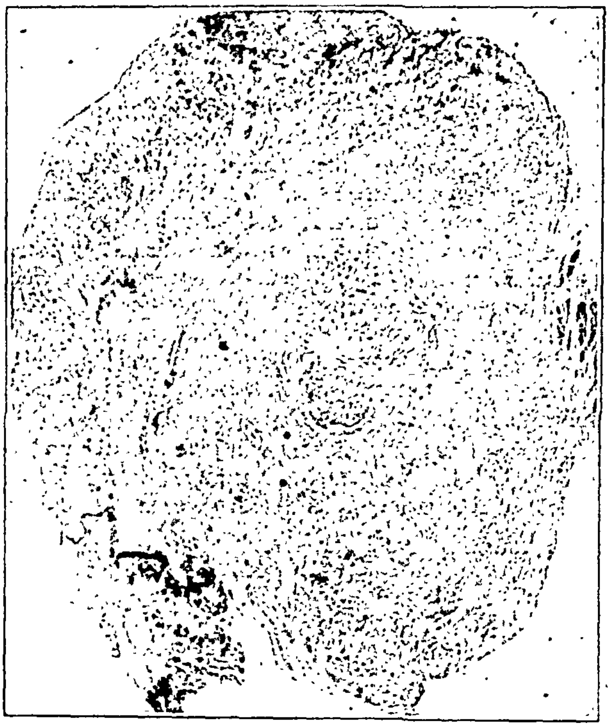

Fig. 3.—Demonstration of the independence of enlargement and of the true prostatic glands: photomicrograph of a section identical with the area of figure 4, showing the nodular enlargement above the compressed prostatic tissue forming its false capsule (specimen of Le Duc[1]).

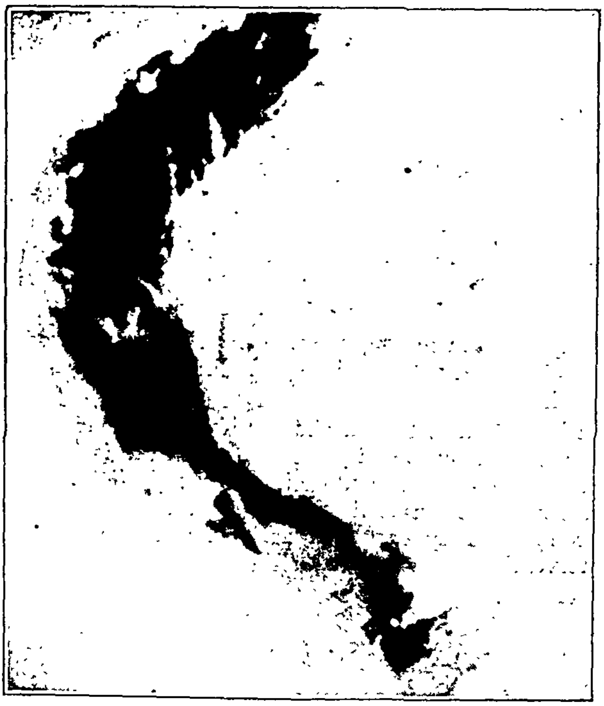

Fig. 4.—Photograph of the same area as figure 3 after a true prostatic duct has been injected with India ink and the specimen cleared, showing how the unrelated enlargement squeezes the glandular tissue.

Unfortunately only the early lesions near the surface of the posterior portion are palpable per rectum. All other lesions, no matter where they start, will extend in time to involve the posterior portion and be palpable, but their diagnosis then is late. As in cancer anywhere, it is the early lesion which is most suitable for radical surgical intervention, the late lesion being incurable.

The approved use of endocrine therapy in the treatment of cancer of the prostate in recent years has so changed the problem that almost every one seems willing to rely on it alone. The relief of urinary obstruction when it occurs, as it usually does sooner or later, is purely palliative whether secured by transurethral resection or by perineal or suprapubic enucleation. None of these surgical methods for the relief of obstruction cures the cancer. The question which endocrine therapy has raised, then, is whether early diagnosis and radical surgical procedures are still applicable in its treatment.

A study of past experiences will give a better understanding of the problem, and comparison as far as possible of the various results will give one the opportunity of drawing one's own conclusion in regard to the place early diagnosis and radical surgery should take in it.

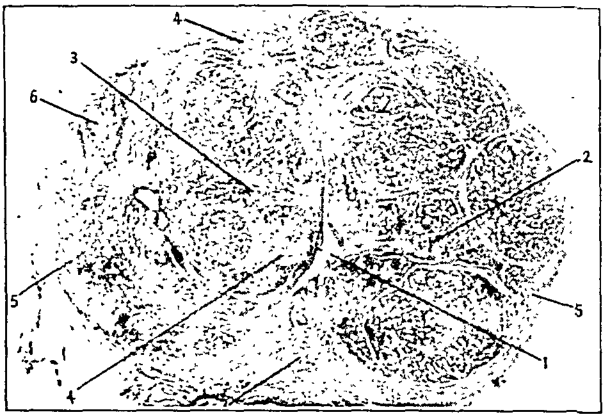

Fig. 5.—Photomicrograph of a cross section of a multilobulated enlargement with two occult primary lesions, neither palpable (from Vernet[30]): 1, urethra; 2, enlarged right lobe; 3, enlarged left lobe; 4, primary cancerous lesion in the left lateral portion, far anterior and commissural; 4′, primary cancerous lesion in left posterior portion next to verumontanum; 5, compressed prostatic glands; 6, primary cancerous lesion in left anterolateral region, and 7, infiltrated space which corresponds to the ejaculatory tubules. Not one of these three widely separated lesions (4, 4′ and 6) of cancer would be palpable per rectum.

First, what is known about cancer? Second, what happens without any treatment or with the ineffective methods of roentgen and radium therapy? Third, how effective is endocrine therapy? Fourth, what has been accomplished by early diagnosis and radical surgical intervention?

1. *What is known about cancer?*

With the remarkable lengthening of the expectancy of life (from 47 years in 1900 to near 67 years in 1947) there has been an alarming increase in the number of deaths from cancer, which now takes a toll of life in this country second only to cardiovascular disease. About seventeen million of the approximately seventy million males in the United States are over 50 years of age. The incidence of cancer of the prostate in this group is variously estimated from postmortem observations (Rich,[12] Kahler,[13] Gaynor,[14] Moore,[15] Myers[16] and Baron and Angrist[17]) of random sections as 14 to 29.4 per cent, or as high as 46 per cent if serial sections have been studied (Baron and Angrist,[17] 1941). This means that at least three to five million and possibly as many as eight million Americans now have cancer of the prostate.

Cancer differs little here pathologically from cancer elsewhere. Rare forms are the sarcomas and medullary carcinomas. Scirrhus and adenocarcinomas are the common forms and give the characteristic stony hardness on rectal palpation. Further detail leads to controversy, and yet none of the points at issue affect in one way or another the final conclusion in regard to radical surgical procedures.

One of these differences of opinion is in regard to the place of origin, which is extremely important in its relation to early diagnosis. It is almost universally agreed that primary cancer arises in the prostate gland unrelated to enlargement, which arises from the periurethral glands. It seems reasonable to conclude that cancer may start in any portion of this part of the gland. It then spreads within its capsule, so that no matter where it started the posterior portion is involved before invasion of the seminal vesicles. Earlier authors, notably Geraghty[18] (1922), were misled by this fact into believing that all cancers arose in this so-called posterior lobe, but Kahler[13] (1939) in a pathologic study of autopsy material found more primary lesions in the anterior and lateral regions together than in the posterior. An anterior or posterior position would still be in the right or left component of the gland, which has developed on lines of bilateral symmetry. Gaynor[14] (1938) located 98.5 per cent of 203 primary cancers in the periphery of the portion involved and, with others, inferred that atrophy first starting in the periphery was related in some way to the onset of cancer. This location, however, gives the advantage of being palpable per rectum only when located posteriorly. Not all are so located. Hence, the problem of early diagnosis is not only the discovery of the primary lesion by rectal palpation but also the development of methods by which the occult forms of cancer which are not palpable may be discovered (fig. 5).

Another difference of opinion is in regard to the onset of metastasis. Involvement of the perineural lymphatics is one of the earliest changes in cancer of the prostate, occurring, according to Kahler[13] (1939), in "practically all of these cases." This fact would seem to weaken if not annihilate the argument for radical surgical intervention. Opponents believe that lymphatic invasion means metastasis and therefore, since neither the primary nor secondary lymph zones of the prostate can be removed, an operative procedure is useless even with early diagnosis. They overlook the fact, however, that this early invasion of lymph spaces surrounding the nerves is confined within the true capsule of the prostate for a long time. Extension into vesicles, invasion of distant lymphatics and of bones and viscera by way of the blood stream are late manifestations (Batson,[19] 1940). Complete removal and cure of the lesion while it is limited within the prostate is possible and has been accomplished repeatedly, even when perineural lymphatics in the capsule have been invaded.

2. *What happens without any treatment or with the ineffective methods of roentgen and radium therapy?*

The onset of cancer of the prostate is elusive, without signs or symptoms, and an estimation of the period from beginning to end is presumptive. The many reports on the duration of life from diagnosis to death are deceptive, in that the majority of cancers were recognized late in the course of the disease. When the facts about occult carcinoma and metastasis are explored, it seems probable that the disease may exist for many years without causing symptoms or spreading beyond its place of origin. This delay prolongs the period for making an early diagnosis and should incite an extra effort to improve one's methods of diagnosis so that full advantage of it be taken, provided of course that early diagnosis and radical surgical methods will cure the disease. Particular studies of what happens without treatment are few. The number of patients who have been followed through to death is hardly large enough to give an exact picture, and the conclusion is further obscured by the difficulty of dating the onset. Two thirds of the patients followed by Bumpus[20] (1926) with metastasis on examination were dead within nine months, and 58 per cent without metastasis were dead one year after the examination which disclosed the presence of cancer. With no subdivision with respect to having or not having metastasis, Vest and Frazier[21] (1946) have followed 74 patients for nine years, by which time all but 2 were dead. Eleven, or about 15 per cent, had died of other causes. Fifty-two, or 70 per cent, were dead within three years. Of the remaining 20, 3 died in the fourth, 13 in the fifth and 2 each in the sixth and seventh years. Only 6, or 8.1 per cent, survived five years.

[19] Batson, O. V.: The Function of the Vertebral Veins and Their Role in the Spread of Metastases, Ann. Surg. 112:138-149, 1940.

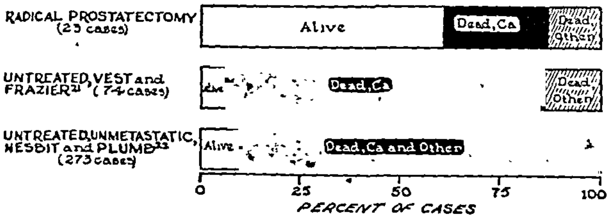

Fig. 6.—Comparative survival, five year series, demonstrating the superiority of early diagnosis and radical treatment over no treatment (from Hinman and Hinman,[25] 1947).

Of the 273 untreated patients without evidence of metastasis studied by Nesbit and Plumb[22] (1946) only 27, about 10 per cent, had survived five years; and of 544 hospital patients with untreated carcinoma of the prostate, Griswold[23] (1946) found only 38, or about 7 per cent, who had lived five years after the diagnosis had been made.[20] To judge from foregoing statements, between 90 and 95 of every 100 men will succumb within five years of the time cancer strikes them. The expectation of life at the age of 60 is 17 years; at 65, 14; at 70, 11, and at 75, 8 years.[24] The mortality rate from all causes over this 15 year period when cancer is most frequent goes up from 2.817 at 60 to 9.178 per 100 at 75. Of 100 men at age 60, between 80 and 85 will be living five years later; but if all at age 60 had had a prostatic cancer, more than that many would be dead. In other words, 10 to 15 of 100 men with cancer at age 60 will die from other causes and 80 to 85 will die from cancer within five years. This big difference in the mortality rates between a group without cancer and a group with cancer shows the error of the general attitude of indifference which arises from a belief that these men haven't long to live anyway.

3. *How effective is endocrine therapy?*

None of the experiences with castration and endocrine therapy have covered a five year period (table 1). Nesbit and Plumb[25] (1946) reported a series of 75 patients treated by castration and closed thirty-five months. Eighty-five per cent of the 33 with metastasis and 52 per cent of the 42 without metastasis were dead. Vest and Frazier[21] (1946) studied the results of castration in 74 patients, closed for two years, 28 with and 46 without metastasis. Of the former group, 8 died the first year, 8 the second, 3 the third and 1 the fourth. Three died of other causes and 5 were still living. Of the latter group, without metastasis, 2 died the first, 3 the second and 7 the third year. Seven died of other causes and 27 were living. Sixty-two per cent of Greene and Emmett's[26] (1946) series of 219 patients were dead within three years after bilateral orchiectomy. The real benefit that most patients with advanced cancer of the prostate derive from hormonal therapy must not be minimized. The relief from pain, the improvement in urination with recession of the local growth and the gain in general health are often remarkable. The indications are, however, that in a five year period almost as many will die as in the untreated series. The immediate benefits are not permanent, and the cancer may show an increase of virulence later. Most urologists, therefore, hesitate to use this method of treatment for early cancer.

4. *What has been accomplished by early diagnosis and radical surgical intervention?*

As already stated, only about 5 in every 100 men with cancer of the prostate are seen early enough to justify radical surgical procedures. Even so, experiences with the operation are sufficient to prove its usefulness (table 2). Colston[27] (1945) has reported

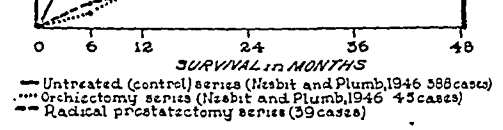

Fig. 7.—Comparative survival, shorter term (unclosed) series, demonstrating the superiority of early diagnosis and radical surgical treatment over orchiectomy (hormone therapy) in the treatment of cancer of the prostate (from Hinman and Hinman,[25] 1947).

48.2 per cent five year cures; and my associate and I[28] in a series of 25 patients operated on five or more years ago reported 56.5 per cent alive, 1 after seventeen years. The comparative survivals of a closed five year series are shown in figure 6 and for the shorter term (unclosed series) in figure 7.

In spite of this evidence, less than 5 of every 100 prostatic cancers are diagnosed early, and the hidden position at the start will not account for the 95 per cent of failures. Many physicians, suspecting cancer or even being sure of it, keep silent, because they know of nothing better, or refer the patient to a member of that large group of urologists who neither advocate nor perform radical surgical operations.

Cancer involves the prostatic glands first, arising as a rule near the periphery of that portion involved, and it grows slowly in the beginning, giving plenty of time for early recognition. If it is located in the posterior portion it may be palpable per rectum. If in the lateral, anterolateral or median portion it may be suspected and discovered by other methods.

The early lesion in the posterior portion gives the sensation of stony hardness. It feels flat rather than spheric (inflammation). It is just beneath the capsule, more superficial than deep, and has a sharp edge or corner. It is perceived best with the patient kneeling forward with hands on a chair or elbows on a table, feet apart. Local lesions of inflammation (particularly tuberculosis, which is rare) are rounded or nodular, and a roentgen picture of the area is always indicated in order to rule out the presence of stone as the cause of the induration. When the observations are characteristic or suggestive enough, the patient should be prepared for the perineal operation at which the area is exposed, a biopsy of it taken and examined immediately by frozen section. If positive, radical removal is completed. If negative, the wound is closed and the patient is up and out of the hospital a few days later. An associated enlargement, which is so frequently present, can be enucleated as in perineal prostatectomy, or if the age of the patient and the small size of the enlargement indicate its removal preferably by transurethral resection, this can easily be done at once through an opening in the urethra before closure of the perineum. Needle biopsies are misleading and have been largely abandoned.

For the early recognition of those primary lesions which cannot be palpated per rectum, two disciplines have been developed through experience. In the past ten years my own records show 43 cases which were unsuspected on rectal palpation before operative intervention. They were discovered by microscopic study of material removed at transurethral resection or of the specimen after perineal or suprapubic enucleation for enlargement. These cancers had invaded the enlargement at its periphery (see 6 on figure 5); they started in the parenchyma of the gland compressed by the enlargement to form its false capsule. Resectionists, therefore, should put aside for particular microscopic search the material removed from the deeper peripheral portions of the enlargement.

The literature is full of reports of malignant degeneration and of tumors arising in areas of benign prostatic enlargement. There is reason to suspect that neither occurs, or at least rarely. Reports like Flynn's[29] (1946) of death from cancer of the prostate nine years after the detection of occult cancer in the specimen removed by suprapubic prostatectomy do not mean nine years' survival with cancer. Pathologists repeatedly have demonstrated the multicentric nature of this lesion. Moore[15] (1935) found 3 widely separated areas in 4 of his cases and 2 areas in 7 others. Ten patients of Gaynor's[11] (1938) series had multiple lesions. Many writers, notably Vernet[30] (1944), have expressed the belief that enlargement is never a focus. Even if this is only partially correct, every suprapubic and perineal prostatectomy should be followed by a careful search of the surface of the specimen and of the cavity left after enucleation, and a biopsy with frozen section of any areas at all suggestive should be made. A cure by radical removal is then possible (fig. 8).

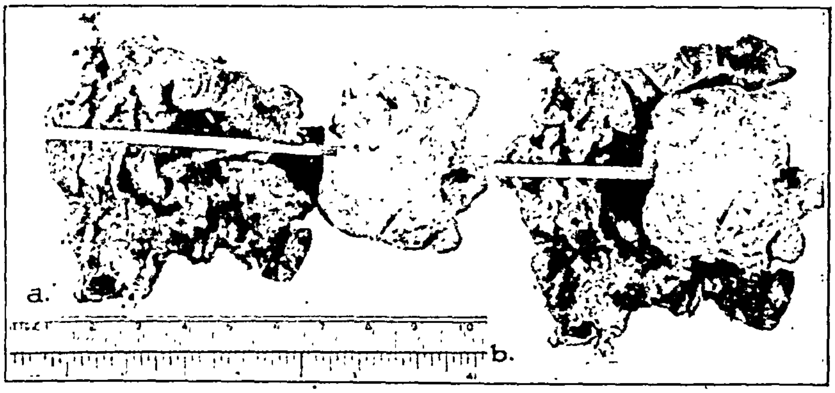

Fig. 8.—Cancer was unsuspected before perineal prostatectomy for enlargement; enucleation from the neck of bladder on right was found to be difficult, and the area felt indurated. A specimen was immediately taken for biopsy; cancer was found on examination of a frozen section, and radical removal of the whole prostate with seminal vesicles was completed. (*a*) Photograph of gross specimen, whole prostate, vesicles and enlargement. The probe is through the enlargement removed en masse; the slot at the upper part of cavity is where the biopsy specimen was taken. (*b*) Photograph taken after the enlargement had been replaced in the cavity from which it had been enucleated. The primary lesion in the right anterolateral portion of the true prostate had only invaded the neighboring area of enlargement. A cure is probable, since there is no evidence of metastasis.

All the evidence now available indicates that to discover cancer while it is limited within the capsule of the prostate is an early diagnosis; that radical surgical intervention at this time will cure over 50 per cent of these patients, and that to increase the number of early diagnoses above the present dismal 5 per cent is a worthy effort.

It is evident also that benign enlargement and carcinoma are distinct and separate lesions of the prostate, even though they commonly occur together.

Brucellosis.—Alice Evans first identified brucellosis, determined that it and Malta fever were identical and proved that this infection and Bang's disease in cattle were caused by the same organisms. The huge program of the Department of Agriculture to clean up infected herds is based mainly on her discovery.—Paran, Thomas: Research and Total Health, *M. Annals District of Columbia,* June 1947.

METHOD OF TREATING MASSIVE OBSTETRIC HEMORRHAGE

JOHN TOTTERDALE COLE, M.D.
New York

Today, hemorrhage outranks all other single causes of maternal death in the United States. Great loss of blood is an ever-feared complication of pregnancy, and when it occurs it creates an immediate emergency which must be met promptly and effectively. It is the purpose of this paper to outline the method of blood replacement which is used at the Woman's Clinic of the New York Hospital.

There has been little clinical study of the early phases of hemorrhagic shock, while an abundance of literature exists describing experiments which have been performed on laboratory animals. Until rather recently the accepted treatment of this type of shock included use of such measures as the Trendelenburg position, oxygen, blood, plasma, dextrose and isotonic sodium chloride solutions, adrenal preparations, morphine, extremity binders and external heat. Subsequent research and clinical experience has cast doubt on the efficacy of all these forms of therapy except blood and plasma. In several instances investigation has indicated not only that certain forms of treatment are of questionable value but that the measures are actually deleterious. So it remains that the basis of successful therapy is the rapid restoration of blood volume by the intravenous use of blood or plasma, preferably the former.

PREVENTION

The best treatment of shock is prevention by the early use of blood transfusions and adherence to the principles of good, atraumatic surgery with close attention to hemostasis. Absurd, yet impressive, is the statement that hemorrhagic shock is caused by the loss of one drop of blood, and since the physician does not know which drop, he should save every drop that he can. When loss of blood is not checked hemorrhagic hypotension, if not treated, may progress rapidly to impending shock and the latter to irreversible shock, from which recovery is impossible.

TREATMENT

Preliminary Typing of Blood.—For over three years it has been the practice in this hospital to determine the blood group and the Rh type of all patients at their first antepartum visit. In an earlier publication the value of this procedure was indicated, and I now wish to emphasize it again. In massive hemorrhage, as will be shown, the time factor is of great importance, and any measure directed toward obviating delay in transfusion should not be overlooked.

Precautionary Measures.—It has been our policy to cross match the blood of all patients prior to delivery if it appears that a large loss of blood may occur. Thus, in cases of twins, hydramnios, myoma uteri, varicosities of the vulva, excessive size of the infant, manual removal of the placenta, or when a difficult forceps delivery is anticipated, the blood of the patient will have been cross matched during labor, and 1 or more pints of blood will be held on call for immediate use at the central blood bank. In the case of cesarean section it has long been a clinic rule that the operation is not to commence until 1 pint (473 cc.) of suitable blood is present in the operating room. Recently precaution has gone one step further. The intravenous administration of sixth-molar sodium lactate solution is started at the time of operation, using a recipient transfusion set and a needle of adequate caliber. Thus, if a transfusion is needed during the cesarean section, a search for veins will not be necessary.

Measurement of Blood Loss.—The general tendency is to underestimate the quantity of blood loss. For this reason it is understandable, yet regrettable, that maternal deaths have been recorded in which the hemorrhage occurred from an episiotomy wound. Pastore[1] has emphasized the importance of measuring the loss of blood, and in massive hemorrhages a fairly accurate knowledge of the volume of blood lost serves as a guide to further treatment. On the other hand, the amount of blood lost is not a good measure of the patient's condition and many times it does not affect the final outcome. This is evident when one considers that deaths are reported in which the loss of blood was as little as 500 cc., and other patients have survived after losses of over 3,000 cc. of blood. Many variables may be present which will influence the individual patient's tolerance of hemorrhage: the age, weight, degree of hydration and general physical condition of the patient, the rapidity of loss of blood and similar factors.

Control of Hemorrhage.—Numerous articles describe various methods of controlling hemorrhage. When massive bleeding has occurred and the patient is in a critical condition, care should be exercised in selecting a means of checking the hemorrhage which will be rapid, effective and atraumatic. Every attempt should be made to shorten the duration of anesthesia by avoiding surgical procedures which may well be postponed to a time when the patient's condition has improved. At cesarean section, once hemostasis is assured the abdomen should be closed by the most rapid methods. In delivery which has been accomplished from below, needless suturing may prove dangerous, since packings will temporarily control bleeding. Trauma and loss of time are to be guarded against at every turn.

The Time Factor.—In the treatment of hemorrhagic shock delay in initiating appropriate therapy is hazardous. Many times it is a fatal error. The delay may usually be traced to ineffectual methods of transfusion, optimistic estimates of the amount of blood lost and hopeful waiting for the patient herself to overcome irreparable blood loss. Again, the surgeon who overlooks a primary hemorrhage resulting in hemorrhagic hypotension may suddenly be faced with a secondary hemorrhage and irreversible shock. It has often been observed that the longer a patient is in a state of shock the more difficult treatment is and the more unfavorable the prognosis. It is my belief that the time factor is not generally appreciated. Its importance will be graphically shown later.

Med. **35:** 390, 1939.

The Obstetric Blood Bank.—It seems almost unnecessary to state that the development of blood banks has done much to reduce the number of hemorrhagic fatalities. The New York Hospital has been fortunate in having a large, active, general blood bank. In spite of these facilities it has been found most useful to have a small obstetric blood bank on the delivery floor itself. This bank contains 2 pints (946 cc.) of type O, Rh negative, citrated whole blood which has been treated with Witebsky blood group specific substance to eliminate anti-A and anti-B factors. Two pints (946 cc.) of commercial dried plasma are also held in reserve. This blood may be used for any patient without preliminary typing or cross matching and is replaced from time to time as it ages. Any unit removed from this bank is used only in an emergency, and the unit must be immediately replaced.

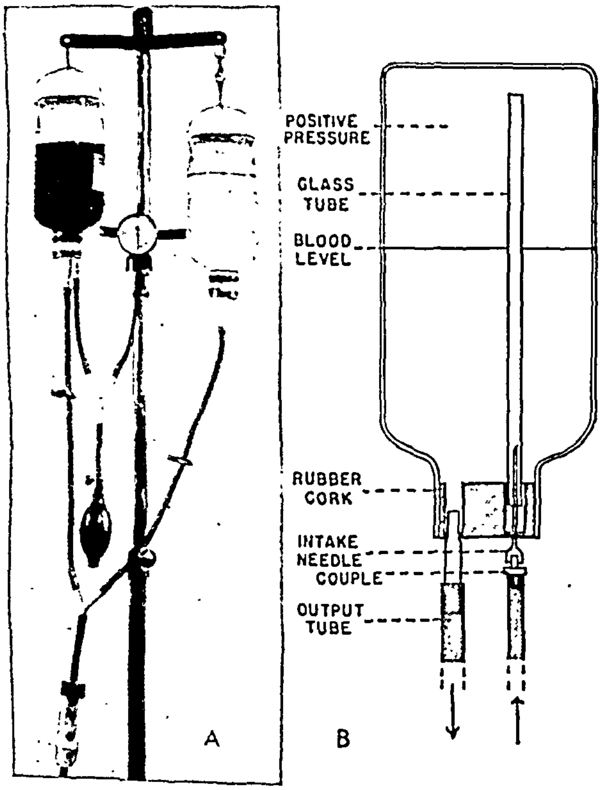

Fig. 1 *A.*—Photograph of standard, closed method transfusion set with simple pressure attachment in place. The left flask contains blood; the right flask contains sixth-molar sodium lactate solution. They are connected by the lower Y tube to a filter from which solutions pass to the patient. The central Y tube connects a sphygmomanometer bulb, aneroid meter and the air-intake needle of the blood bottle. The connection to the air-intake needle may be made by slipping the tubing over the needle or by employing the metal coupling from a sphygmomanometer. The coupling makes an exact fit with a standard needle. *B,* detailed sketch of pressure connection to the blood bottle.

A Method of Rapid Transfusion.—When a patient is suffering shock from massive blood loss, the ordinary drip method of blood transfusion is wholly unsuitable. Studies here indicate that if recovery is to occur, at least 40 per cent of the total blood lost should be replaced during the first hour following the initial hemorrhage. Rapid treatment should not be stopped until there has been a definite response in the blood pressure, and thereafter blood may be given by the usual methods until there has been 100 per cent or more replacement. When an exceedingly large volume of blood has been lost, such rapid replacement is not possible by the drip method. Consequently, during the past three years, a simple pressure mechanism has been added to the ordinary transfusion apparatus (fig. 1).

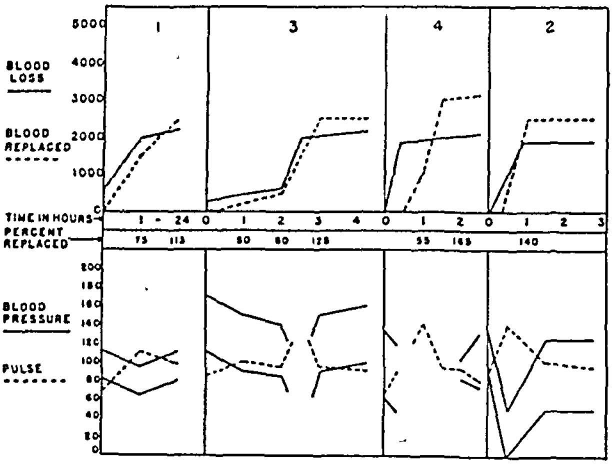

Fig. 2.—Rapid transfusion: the shaded area indicates blood deficit. Cases 1 and 3 illustrate the advantages of anticipating hemorrhage. Although the blood losses were 2,100 and 2,200 cc., blood was given almost as rapidly as it was being lost. In case 1 there were only slight fluctuations in pulse and blood pressure readings; in case 3 the readings were unobtainable for a very short period of time. In cases 4 and 2 the hemorrhage, although it was not anticipated, was treated promptly and more than adequately. Changes in pulse and blood pressure were much more pronounced. The total blood losses were 2,100 cc. and 1,900 cc., respectively. In all 4 cases the blood replacement was 50 per cent or more in the first hour.

Using this apparatus and maintaining a pressure of 120 mm. of mercury in the bottle of citrated blood, 500 cc. of blood may be given quite rapidly (in seven to ten minutes using an 18 gage needle, in two to five minutes using a 15 gage needle). Veins of the arm or hand are usually selected as the site for trans-

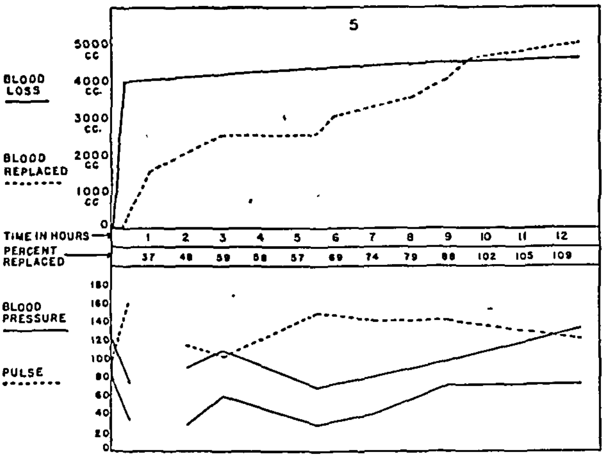

Fig. 3.—Rapid transfusion: the shaded area indicates blood deficit. Case 5 illustrates the dangers of undertreatment. The patient suffered a rapid, massive hemorrhage of 4,000 cc., and a total blood loss of 4,600 cc. The emergency was met promptly and treated effectively for three hours. At this point, 59 per cent of the lost blood had been replaced and a satisfactory clinical response had occurred. From hours three to five and one-half an optimistic attitude was adopted, and no further blood transfusions were given during this period. At the end of five and one-half hours a rising pulse rate and falling blood pressure ushered in a secondary phase of shock which was most difficult to overcome, and which nearly proved fatal. At five and one-half hours rapid transfusions were again started; they were continued to nine and one-half hours, at which point 100 per cent blood replacement had been achieved. See figure 6.

fusion. Saphenous and femoral veins, although of better caliber, are usually not readily available during obstetric procedures.

Alkali Agents.—Dextrose and isotonic solutions of sodium chloride have been all but discarded as therapeutic measures; instead, sixth-molar sodium lactate solution is now used. It has long been known that a straight line relationship exists between the fall in blood pressure and the alkali reserve. Experimental evidence discloses that if the acidosis of shock is not combated it may be a major factor in so-called irreversible shock by featuring in myocardial and capillary damage.[2] By definition, recovery from irreversible shock is impossible; but there is evidence that the administration of alkali agents proves useful in delaying the onset of irreversible shock until the more effective agents, such as blood and plasma, are available in sufficient quantity.[3] The secondary purpose in giving alkali agents is to combat transfusion reactions which might presumably occur when multiple transfusions are administered.

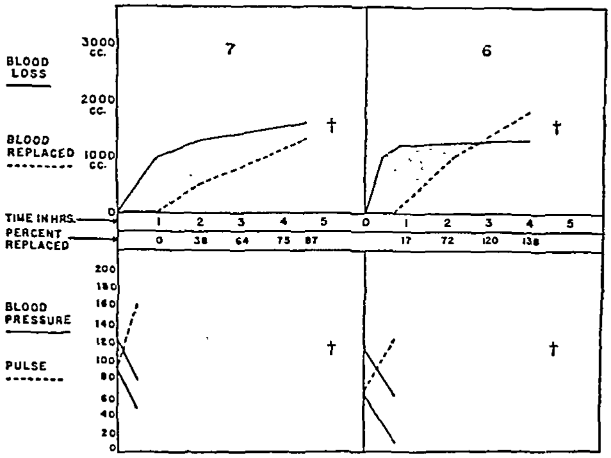

Fig. 4.—Drip method transfusion: the shaded areas indicate blood deficit. Cases 7 and 6 illustrate classic hemorrhagic fatalities. In case 7 the blood loss was 1,600 cc., and in case 6 the loss was 1,300 cc. Note that in each instance transfusions were started three-quarters of an hour or more after the initial hemorrhage. Note also that at the end of an hour only 0 per cent and 17 per cent replacement had been accomplished. In case 6, at four hours 138 per cent of the blood lost was replaced, yet the patient succumbed at this point. In both cases the pulse and blood pressure readings were never obtained after the hemorrhage.

RESULTS

The previously described methods have been used on both the obstetric and gynecologic services. Since the method was adopted there have been no deaths from hemorrhage during 3,600 major and 3,900 minor gynecologic operations. On the obstetric service 1 death due to hemorrhage (case 8) has occurred during 14,000 deliveries. While the method has been in use there have been 250 postpartum hemorrhages (600 cc. or more blood loss).

In this study cases in which massive hemorrhages (1,300 cc. or more blood loss) occurred have been selected at random. In cases 6 and 7 the patients were not treated by the method described herein; thus, the response to the ordinary drip method of transfusion and the pressure method of transfusion may be compared.

CONCLUSIONS

1. The importance of hemorrhage—the outstanding cause of maternal deaths in the United States—should make further investigation imperative.

2. Quick control of hemorrhage by the least traumatic method and rapid replacement of the blood lost remain the best means of treatment of hemorrhagic shock.

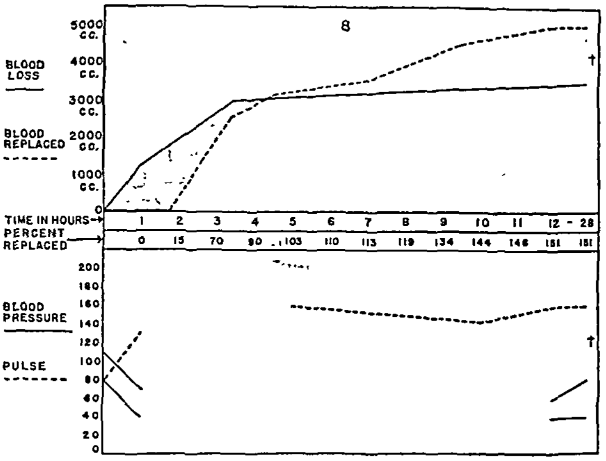

Fig. 5.—Rapid transfusion: the shaded area indicates blood deficit. In case 8 the blood loss was 3,500 cc. The importance of the time factor is obvious. Rapid transfusions were not started until one and three-quarters hours after the initial hemorrhage, which was followed by a large secondary hemorrhage. The rapid transfusion method was continued until almost 100 per cent of the lost blood had been replaced and was then supplanted by the drip method until a response in pulse and blood pressure was recorded. At twenty-eight hours the patient suddenly expired, although there was 151 per cent blood replacement.

3. An effective plan of treatment advises: preliminary typing, precautionary measures, accurate measurement of blood loss, effective hemostasis, the development of an obstetric blood bank, recognition of the importance of the time factor and rapid transfusions in conjunction with the administration of an alkali agent.

4. A rapid method of performing blood transfusions is described.

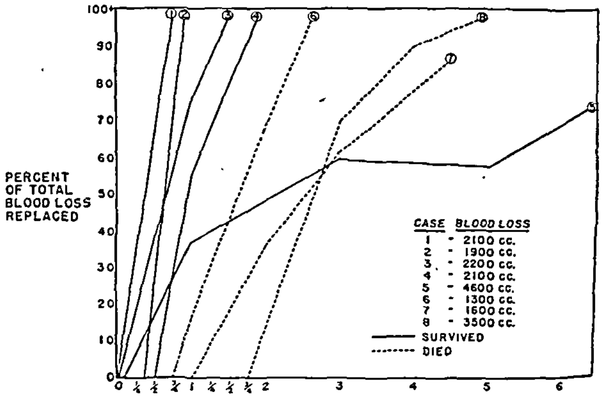

Fig. 6.—A combined graph of cases 1 to 8 illustrating the importance of time in blood replacement therapy. Transfusions were started in less than three-quarter hour, and at the end of one hour blood replacement was 50 per cent or better in all patients who survived except in case 5. In case 5 (see figure 3) 38 per cent blood replacement was accomplished at the end of the first hour, but treatment was inadequate after three hours. The patient went into a secondary phase of shock from which she gradually recovered after further rapid transfusions. Cases 6, 7 and 8 were fatal. Note that treatment was not started until three-quarters of an hour or more had elapsed since the initial hemorrhage. In the three cases blood replacement approached or bettered 100 per cent. In cases 6 and 7 the patients were treated by the drip method; in case 8 by the rapid transfusion method.

MENINGITIS DUE TO CANDIDA (MONILIA) ALBICANS WITH RECOVERY

S. L. ZIMMERMAN, M.D.
LLOYD FRUTCHEY, M.D.
and
J. HEYWARD GIBBES, M.D.
Columbia, S. C.

Reports of meningitis due to Candida (Monilia) albicans have been rare. A review of the literature reveals that only 3 cases have been reported until the present time.[1] All have ended fatally despite therapeutic measures which consisted of iodide preparations, sulfonamide drugs, high voltage roentgen ray and others. In the most recent case, which was reported by Morris and associates,[1c] the patient had widespread fungous disease involving the skin, oral mucous membranes and nails. In this case the organism was demonstrated on direct smear in the spinal fluid Clinically, because of a high cerebrospinal fluid pressure, headache, papilledema and results of ventriculographic studies, a diagnosis of intraventricular block was suggested. This was somewhat confirmed by the postmortem observation of a granulomatous lesion involving the ependymal structures. This case had many similarities to the one reported here, the points of similarity being the meningeal involvement, the involvement of the mucous membrane, the ease with which the fungus was demonstrated both from the cerebrospinal fluid and the oral mucus membranes and the cytologic and chemical study of the spinal fluid. It differed in that this patient survived. Treatment in the present case consisted in the administration of iodide compounds, sulfonamide drugs and streptomycin.

It is believed that this is the first case of meningitis due to C. albicans with recovery which has been reported. The difficulty in concluding that the streptomycin has been the important factor in recovery will be apparent as the case is reviewed. Further discussion on this point will follow later. This is the first case in which streptomycin has been used, and therefore a report of the case is warranted. Because of the apparent rarity of the disease entity, the recovery alone, regardless of the therapeusis involved, is worthy of note.

The association of thrushlike lesions of the oral mucous membrane with ill fitting dentures has been noted in the past. The frequency of thrush and the rarity of systemic fungous disease as a complication is not entirely explained. The pathogenesis of meningeal involvement from the oral pharynx is not definitely known, two routes of spread having been suggested: first, by way of the blood stream and second, by direct extension through the cribriform plate of the ethmoid bone. We cannot, as a result of the study of this case, add any information on this point. Smith and Sano's[1a] demonstration that meningitis can be produced in rabbits by the intravenous injection of monilia previously obtained from a human subject lends support to the hypothesis that the extension is blood-borne.

REPORT OF CASE

History and Examination.—C. A. F., a white man aged 28, a textile worker, was acutely ill when he was admitted to the hospital on June 27, 1946. The past history was entirely noncontributory except that the patient had had malaria. He had always been frail, his average weight having been about 105 pounds (47.6 Kg.), his height 5 feet 4 inches (162.5 cm.). His service in the army included tours of duty in California, New Guinea and the Philippine Islands. There was a history of moderate alcoholic intake since separation from the service in December 1945.

One week prior to admission he noticed mild generalized headaches, which became increasingly severe and finally made it necessary for him to go to bed on June 25. On that date he became febrile and had sensations of chilliness. On the day of admission he noticed pain in the back of his neck. He had vomited prior to admission, but this was apparently not of the projectile type. He had become progressively drowsy during the day and had been restless and delirious at night during the two days immediately preceding admission.

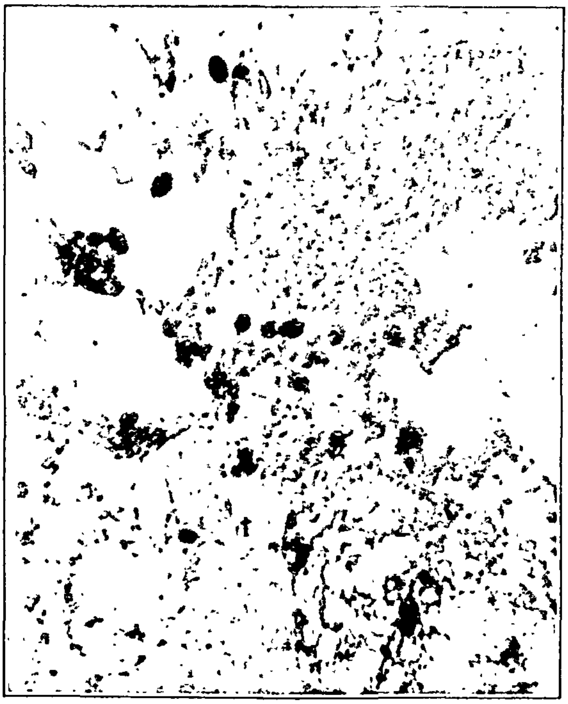

Fig. 1.—Photomicrograph of direct smear of spinal fluid; note the large round budding cells.

Physical examination revealed an acutely ill, dehydrated, febrile white man who was delirious. Hiccoughs were present at the rate of six to ten per minute. His temperature was 101 F. rectally. The pulse rate was 102 and the respiratory rate 25 per minute. The disk margins were blurred and the retinal veins distended; the arteries were within normal limits. Examination of the mouth and pharynx revealed that white patches which varied in size from 0.5 to 2 cm. in diameter covered the soft and hard palate, the posterior pharyngeal walls and the base of the tongue. The surfaces of the smaller patches were adherent to the underlying structures and were slightly raised; the larger patches were slightly depressed, were loosely adherent to the underlying structures and left a gangrenous base when removed. The neck was stiff. The Kernig sign was bilaterally positive. The superficial reflexes were present. The deep reflexes were absent. Extreme lethargy alternated with

active delirium. More careful neurologic examination was not possible at the time. The lungs and heart were normal. The blood pressure was 118 systolic and 72 diastolic. The abdomen, except for a distended bladder which on catheterization yielded 36 ounces (1,065 cc.) of urine, was negative. There was no rash and no evidence of mycotic disease of the skin.

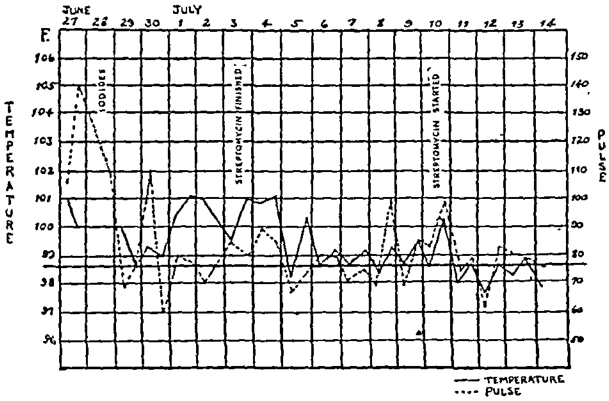

Fig. 2.—Correlation of streptomycin therapy with temperature and pulse rate.

The admitting impression was not definite. Diagnoses of bacterial meningitis, typhus fever, encephalitis and infectious mononucleosis were considered.

Urinalysis was normal. The white blood cell count was 5,500, with 62 per cent polymorphonuclear leukocytes, 32 per cent lymphocytes, 4 per cent monocytes and 2 per cent eosinophils. The hemoglobin was 16 Gm. per hundred cubic centimeters. No Plasmodium malariae were noted. The nonprotein nitrogen level was 31 mg. per hundred cubic centimeters. Smear and culture of material from the mouth and pharynx yielded C. albicans.

Treatment and Course.—A lumbar puncture was performed on June 28. The initial pressure was 270 mm. of water. The manometric determinations were normal. Direct smear, stained with methylene blue, showed large, oval, budding yeastlike fungi (fig. 1). There were 37 lymphocytes per cubic millimeter. The protein level was 186 mg., the dextrose 66 mg. and the chlorides 585 mg. (as sodium chloride) per hundred cubic centimeters. (For this and for the analysis of subsequent lumbar punctures see figure 2.) No pedicle was formed, but the low chloride level in the fluid was suggestive of an acid-fast infection. There were no acid-fast organisms found.

At this time the temperature was 100 F., the pulse rate 120 and the respiratory rate 28 per minute. The patient was semicomatose and hiccoughing. A blood culture was subsequently reported as negative. Solution of potassium iodide, 10 grains (0.65 Gm.) three times a day, was prescribed, and in addition parenteral fluids were administered. One gram of sodium iodide was given intravenously as well. On June 29 the patient appeared somewhat more alert. Oral iodide preparations were given in gradually increasing doses, and the administration of intravenous iodide compounds was increased to 2 Gm. daily and continued practically throughout the entire course of therapy. On this day sulfadiazine therapy was started, 2 Gm. initially and 1 Gm. every six hours day and night. This drug was continued until July 3, at which time streptomycin therapy was begun. A level of 6 mg. of the drug per hundred cubic centimeters of serum was attained. Gentian violet medicinal was applied to the lesions in the mouth and pharynx.

Lumbar punctures were performed on June 29 and 30. The fluid revealed a positive smear and culture on June 29 and a negative smear and culture on June 30. The Pandy test was positive. and the cells increased from 37 to 70 lymphocytes per cubic millimeter. The temperature dropped slightly on these dates. The hiccoughing ceased. The Levinson test was reported negative on June 30. The urine was normal, except that cultures of urine revealed a staphylococcus, infection with which was considered to result from the repeated catheterizations. Agglutination tests for the usual febrile diseases were nondiagnostic. The white blood cell count, red blood cell count and hemoglobin level remained within normal limits throughout the patient's illness.

The temperature again rose, and the patient deteriorated somewhat clinically on July 1 and 2. On July 3 streptomycin therapy was started. The sulfonamide drugs were no longer given, but iodide administration, both orally and parenterally, was continued. The streptomycin dosage and the manner of its administration, as well as the levels of the drug attained in the blood, are indicated on the accompanying table. In addition, the intrathecal administration of streptomycin in doses of 0.025 Gm. initially and then 0.050 Gm. daily for a period of seven days was carried out. The temperature gradually fell, and, aside from one small rise to 100 F. on July 10, has remained normal since. The patient has been under continual observation for a period of four and one-half months. His neurologic symptoms gradually subsided, as did the papilledema. The latter was extremely slow in its subsidence. At present (November 1946) he is entirely asymptomatic, has gained weight and feels "as well as ever." Spinal fluid determinations have returned to practically normal limits during this period. The last fluid was obtained on November 5. The pressure and manometric determinations were normal. The Pandy reaction was negative. There were no cells, although the protein content of the fluid was slightly elevated. The administration of iodide compounds was continued intermittently through October. At present it appears that the patient is cured.

SOME REMARKS ON THE BACTERIOLOGIC DIAGNOSIS

As has previously been stated, direct smear of the spinal fluid and of material from the thrushlike lesions of the pharynx revealed large oval fungi. On culture on Sabouraud's medium and blood plates, incubated at room temperature and at 37 C. for four days, there was luxuriant growth of medium sized, creamy, moist colonies. Smears from these colonies, both wet and fixed, showed oval and round budding cells. Subcultures made on Sabouraud's medium, blood plates and corn meal agar to exclude contamination resulted in the same type of growth. Myceliums were noticed after eight to ten days' incubation, and the subcultures on corn meal agar produced myceliums bearing ball-like clusters of budding cells. Agglutination of the patient's serum against C. albicans was positive in a dilution of 1:40. This was accomplished at Duke University. No facilities existed for the performance of a complement fixation test for monilia.

COMMENT

The point of primary interest in this patient is the fact that he recovered from a proved meningitis due to C. (monilia) albicans. A review of the literature at our disposal suggests that this is a unique experience. Consequently, the treatment employed is reported in detail, and we wish to call attention to some of the implications which it suggests.

The diagnosis was established within twelve hours after the patient's admission to the hospital. He was immediately started on the customary treatment of iodide compounds by mouth and intravenously and the topical use of gentian violet medicinal to the mucous membranes involved. Within forty-eight hours his spinal fluid failed to yield C. albicans on either smear or culture, and his general condition showed some degree of improvement. However, two days later his clinical improvement was not maintained and his temperature reached its maximum point of 101 F. Streptomycin therapy was started the next day and was continued for eight days. During this time he was given 10.2 Gm. of streptomycin. The cell count in the spinal fluid was 900 the day after streptomycin was started and was found to be over 200 on the sixth day after it was stopped. At this time the organisms were again demonstrated in the spinal fluid after having been absent on six examinations covering a period of sixteen days. From this time forward the fluid remained free of C. albicans, and the cell count dropped rapidly. The last examination of the spinal fluid was done on November 5, more than four months after the start of the treatment, and it was found to be normal in every respect except a slight elevation of the protein content. The patient shows no subjective or objective residual indications of the disease.

While the iodide preparations were used intensively throughout the course of this patient's illness, we were not impressed with any indications of benefit from them. We saw nothing to suggest that the sulfonamide drugs, employed for a brief period, in any way modified the course of the disease. Simultaneously with the beginning of streptomycin therapy the temperature became lower. It rose to a little over 100 F. on the day that the treatment was finished, and then became and remained normal. The changes in the spinal fluid and the clinical improvement of the patient were much more gradual. It is, of course, possible that simple drainage of the spinal fluid and natural immunity reactions may have accounted for this patient's recovery. However, there is enough evidence suggestive of the efficacy of streptomycin in this case to warrant its trial in similar infections in the future.

CONCLUSION

In a case of meningitis due to Candida (Monilia) albicans in which recovery is reported, streptomycin therapy may have been of value.

STREPTOMYCIN IN THE TREATMENT OF DRAINING TUBERCULOUS SINUSES

BENJAMIN L. BROCK, M.D.
Chicago

One of the most impressive results in the treatment of tuberculosis in man by streptomycin has been obtained following its use in draining tuberculous sinuses.

Eleven Negro patients and 1 white patient, the majority of whom had multiple, draining, tuberculous, cutaneous sinuses, have been treated with streptomycin in the Veterans Administration Hospital at Oteen, N. C. There were 60 draining sinuses in the 12 patients reported in this series. The average length of time these sinuses existed prior to the institution of streptomycin therapy was twenty-four months. Treatment was started on 9 patients about July 1, 1946. In the other 3 patients it was initiated during the last week in September 1946. All but 2 of the patients had draining sinuses which originated in bone. In 1 of the 2 a sinus developed following laparotomy, and the other had several perineal sinuses originating in the ischiorectal area. All the cases were proved to be of tuberculous origin, either by biopsy or culture of the sinus material. Only 1 of the patients had active pulmonary tuberculosis.

A daily dose of 1.8 Gm. streptomycin, 0.3 Gm. every four hours, was given intramuscularly. Six of the patients received treatment for ninety days. The remaining 6 patients received treatment for one hundred and fifty days with an interruption of three weeks after the first ninety days.

Eleven of the 12 patients with tuberculous sinuses showed outstanding clinical signs of improvement; namely, a sense of well-being, an increase in appetite and a gain in weight. Some of the Negro patients, who were considered to be in a critical condition at the time streptomycin therapy was begun and who were extremely emaciated, began rapidly to gain in weight and have continued to do so. The average gain in weight has been 15 pounds (7 Kg.). Those who were febrile at the beginning of therapy quickly became afebrile and, with the exceptions of the few who had febrile reactions caused by the streptomycin, have remained so.

Certain toxic reactions were observed regularly. None was severe enough, however, to justify discontinuation of the streptomycin therapy. Besides the local reaction incident to the injection of the drug, the commonest clinical reactions have been those of headache and dizziness. Headaches, which have been a regular occurrence in other white patients who were treated with streptomycin because of their pulmonary lesions, have not been complained of by the Negro

The Streptomycin Committee, Veterans Administration, Washington, D. C., cooperated in this research.

From the Department of Medicine and Surgery, Veterans Administration Hospital, Oteen, N. C. Published with permission of the Chief Medical Director, Veterans Administration, who assumes no responsibility for the opinions expressed, or conclusions drawn, by the author.

Dr. Christopher Parnall Jr. assisted me during the early part of this study. Detail phases of this work were handled by Drs. Siegbert Bornstein, Chief of Laboratory, and his assistants; Milton R. Himalstein, Ear, Nose and Throat Department, and Parker D. Elrod and by Lieut. Ernest H. Winterhoff, M. C.

patients in this series, presumably because of the higher threshold for pain exhibited by this race. The average length of time which elapsed before the onset of the so-called vestibular symptom of dizziness was between three and four weeks. This symptom is usually exaggerated in the absence of light. A few of the patients had actual ataxia, and these patients complained of inability to distinguish objects or persons at a distance while in motion. In several instances dizziness has continued as long as three months following discontinuation of streptomycin therapy. The caloric test has regularly revealed a hypoirritability which was apparently equal in both ears and persisted after the cessation of treatment.

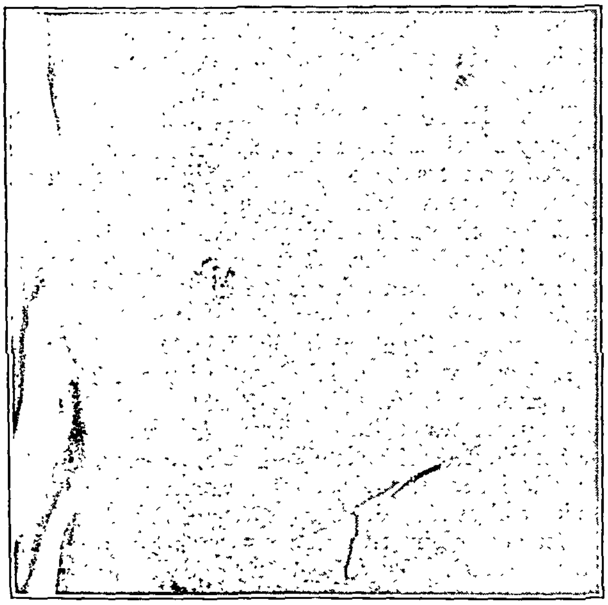

Fig. 1.—W. D., a Negro man aged 22, with draining sinus in the left lower quadrant resulting from wide incision of psoas abscess (June 13, 1946).

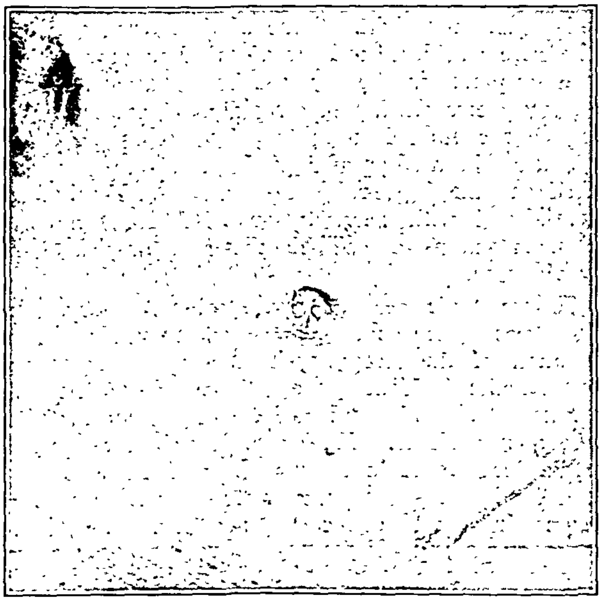

Fig. 2.—Same patient as in figure 1. The patient received streptomycin for ninety days. The sinus closed after eleven weeks. The sinus in the upper right quadrant closed after two weeks of therapy (Oct. 1, 1946).

In 3 of the patients a febrile reaction which occurred shortly after the administration of streptomycin was considered to be due to the drug. Several of the white patients have had a flushing of the skin, but none of the Negro patients has had this reaction. No case of exfoliative dermatitis has been seen.

Transient casts were found in the urine of 8 of the 12 patients. However, no renal damage of a permanent character was encountered. The blood urea nitrogen was not over 15 mg. per hundred cubic centimeters in any instance, and no evidence of hepatic damage was demonstrated.

Four of the patients manifested an eosinophilia of over 5 per cent, which persisted throughout treatment. Most of them had an elevated sedimentation rate at the beginning of treatment, and this was unaffected by the treatment. The streptomycin concentration of blood serum was between 10 and 20 micrograms per cubic centimeter in all cases. All samples of blood were taken two hours after the injection of streptomycin.

These cases have not been followed sufficiently long to determine whether streptomycin has produced a permanent closure of the sinuses, but the promptness with which they healed after the initiation of treatment is one of the outstanding observations in this serie Tuberculous sinuses of several years' duration, originating in bone, in the ischiorectal region or followin laparotomy for appendicitis, have closed within a wee to ten days in some instances. After about three t four days of streptomycin therapy the purulent materia draining from the sinuses became less purulent an smaller in amount. It has also been observed that th induration surrounding the sinus tracts and the tenderness associated with them have disappeared as early as one month after treatment was begun. There has been impressive evidence that closure is prompter when free drainage is present. If small abscesses exist under the skin and the sinus is not draining adequately, the area should be incised and the pus evacuated. The area then heals by healthy granulation. Where necrotic bone or cartilage is present, as for example in a rib or sternum, this necrotic material should be removed. When this is done, streptomycin accelerates healing.

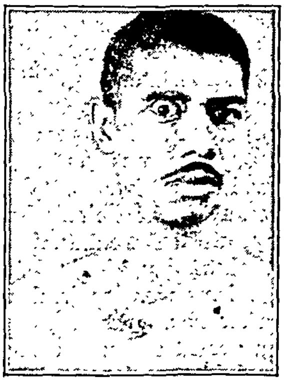

Fig. 3.—M. B., a Negro man aged 23, with orbital tuberculosis with unilateral exophthalmos and active involvement of the eyelid. Some necrotic bone in the orbital region was removed. There was some loss of vision in the involved eye. There was also a draining sinus over the anterior part of the chest (Sept. 1, 1946).

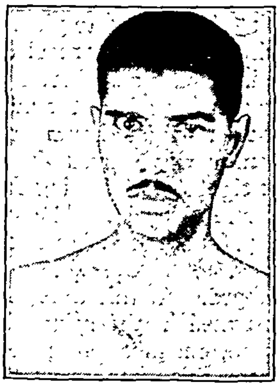

Fig. 4.—Same patient as in figure 3. Drainage from the orbit ceased after twelve weeks, and the sinus over the chest was closed after fifteen weeks. The exophthalmos was reduced so that the patient can almost close the eye. Plastic operation on the eyelid is contemplated. Pronounced regeneration of bone has been observed (Jan. 16, 1947).

When a large cold abscess exists in conjunction with tuberculosis of the vertebrae, there is little tendency for the pus to disappear under streptomycin therapy unless it is evacuated by open drainage. In several cases the abscess has been drained by this method in the groin or on the lateral surface of the thigh. One such abscess pointed in the back opposite the affected vertebrae and was drained by open incision. When these large open sinuses are allowed to drain while streptomycin therapy is being carried out they fill in quickly with healthy granulations and close. There has been no evidence, since closure of such sinuses in these patients, of any recurrence of pus in the paravertebral area or elsewhere. After drainage of the abscesses the patient feels greatly improved clinically, just as would be the case were nontuberculous abscesses drained.

One patient who had unilateral exophthalmos (figs. 3 and 4) and who showed radiographic evidence of advanced destruction of the orbital portion of the frontal bone prior to streptomycin therapy has recently manifested radiographic evidence of extensive regeneration of bone. As yet, however, there has been little evidence of regeneration of bone along the lateral surfaces of affected vertebrae or in ribs partially destroyed by a tuberculous process. This has been particularly true in the case of "punched out" areas in the shafts of long bones.

Nine (15 per cent) of the 60 sinuses closed within one to four weeks and 9 (15 per cent) closed within six to eight weeks after the administration of streptomycin was begun. It required between ten and twelve weeks for 30 (50 per cent) of the sinuses to close, and 11 (approximately 20 per cent) closed within thirteen to twenty weeks after streptomycin was instituted.

Of the sixty original draining sinuses only 1 continues to drain at this time (March 10, 1947) eight months after streptomycin therapy was started. Even this sinus is showing definite improvement since open drainage of the perineum was instituted on Nov. 18, 1946 and since discontinuation of streptomycin therapy on Dec. 26, 1946. The incised area is healthy in appearance, and it is believed that it will be completely closed within a short time.

Of the other sinuses the longest time which has elapsed since closure is eight months; the shortest time two months, and the average time four months.

Chronic Invalids Rehabilitated.—Not quite a year ago, in a VA hospital in Minneapolis, we had a group of 110 World War I veterans who were chronic invalids and bedridden; some had been in the hospital almost ten years. Most of them were helpless, flat on their backs. All were between the ages of 50 and 60. With the medical program as we found it in VA, these veterans could look forward only to staying in a hospital bed until they died. After the rehabilitation program had been going for eight months a check of these patients showed:

25 discharged from the hospital and back home, working at full time jobs.

30 discharged from the hospital and back home working at part time jobs.

40 more just about ready to leave the hospital, with the prospect of taking part time jobs a little later on.

5 expected to leave the hospital eventually.

Only 10 of the original 110 had no prospects for discharge from the hospital. And remember, every one of these patients was over 50 years of age. The thing could not have been done without courage, optimism and a lot of persistent hard work on their part.—Address by Dr. Paul R. Hawley before the twenty-sixth National Convention of Disabled American Veterans.

SYSTEMIC HERPES SIMPLEX (KAPOSI'S VARICELLIFORM ERUPTION)

Moccasin Venom Used in Conjunction with Penicillin in a Severe Case and with Diphenhydramine Hydrochloride ("Benadryl Hydrochloride") in a Mild Case

LESLIE PAXTON BARKER, M.D.
and
EARL S. HALLINGER Jr., M.D.
New York

Since the development of laboratory procedures which demonstrate its presence, the virus of herpes simplex has been found to be the cause of a wide range of infections. It has been demonstrated in such localized lesions as the common fever blister, aphthous stomatitis, acute herpetic gingivostomatitis[1] and paronychia. It has also been recovered from the spinal fluid[2] and brain substance[3] of patients with encephalitis. Since 1941 the virus of herpes simplex has been demonstrated in the cutaneous lesions of those infrequent and grave systemic infections known as Kaposi's varicelliform eruption.

This uncommon syndrome which bears Kaposi's name was first clinically described by him in 1887[4] as a disease resembling chickenpox and occurring in children with allergic eczema. His description of the disease follows:

> The vesicles are as large as a lentil, filled with clear serum, and the majority are umbilicated. They look like varicella vesicles but undoubtedly do not belong to this class. The integument which has been attached in this manner now appears still more swollen, even tense. The little patients have high fever (40 C. [104 F.] or more) and appear very restless. The vesicles develop very acutely (sometimes overnight) in large numbers and often continue to appear in successive crops for three or four days or even a week. Those which appeared first undergo desiccation, rupture and expose the corium, or they become encrusted and fall off. The largest number of these varicella-like vesicles are found on already eczematous skin, but smaller groups appear on the forehead, neck and even the shoulders and arms.

When Barton and Brunsting[5] in 1944 contributed their review of the extant literature on Kaposi's varicelliform eruption, only 67 cases of the disease had been described. According to the Barton and Brunsting study, 53 of the reported 67 cases had occurred as complications of chronic allergic dermatitis. The majority of the remaining cases followed such antecedent dermatoses as seborrheic dermatitis, sycosis vulgaris, simple trauma, impetigo, scabies and the puerperium. Fifty-one of the reported cases occurred in children. The mortality rate was 25 per cent, being much higher in children than in adults. Of the 50 patients whose sex was listed, 30 were male and 20 female.

From the Department of Dermatology and Syphilology, St. Luke's Hospital; attending dermatologist (Dr. Barker) and resident in dermatology (Dr. Hallinger).

[5] Barton, R. L., and Brunsting, L. A.: Kaposi's Varicelliform Eruption: Review of the Literature and Report of Two Cases of Its Occurrence in Adults, Arch. Dermat. & Syph. **50:** 99-104 (Aug.) 1944.

To date, this group of cases reported as Kaposi's varicelliform eruption represents a wide variation of a syndrome. From their description it is difficult to assign all of them to the same clinical category. The variety of names applied to the reported cases also indicate degrees of differentiation. Some of the names under which the disease has been described are: eczema herpetiforme,[1] pustulosis acuta varioliformis,[6] acute vacciniform pustulosis,[7] pustulosis vacciniformis acuta,[8] varioliforme pyodermien,[9] pyodermite post puerperale varioliforme,[10] eczema vaccinatum[11] and dermatitis vaccinica.[12]

Until recently no real cause had been established for any of the various reported cases of Kaposi's varicelliform eruption. Kaposi himself attributed the disease to a fungus. Other writers suggested a pyococcus as the cause. Cases have been described as occurring in persons with chronic dermatitis after vaccination for smallpox or exposure to vaccinia. Consequently the disease has sometimes been considered an unusual reaction to the virus of vaccinia in allergic persons. This assumption has never been established.

Seidenburg[7] in 1941 reported 2 cases, under the name of "pustulosis vacciniformis acuta," in which he demonstrated that rabbits inoculated with material from the cutaneous pustules were subsequently susceptible to the virus of vaccinia but were definitely immune to that of herpes simplex. He reasoned that the results of his cross immunization tests indicated that the disease was probably caused by the virus of herpes simplex and not by the virus of vaccinia. (It is possible that there are two distinct diseases with similar clinical characteristics, one caused by the virus of vaccinia and the other by that of herpes simplex.)

Since 1941 Wenner,[13] Barton and Brunsting,[5] Lane and Herold,[14] Lynch[15] and Blattner[16] and their workers have demonstrated by animal inoculation and immunization tests the presence of the virus of herpes simplex in the cutaneous lesions of patients with Kaposi's varicelliform eruption. Their research has given experimental proof that the virus of herpes simplex is the cause of at least some, if not all, cases of Kaposi's varicelliform eruption.

We think that those cases from which the virus of herpes simplex has been recovered should no longer be classified in the general category of Kaposi's varicelliform eruption. Because these virus infections have definite clinical symptoms of a systemic disease in addition to their diffuse cutaneous manifestations a more appropriate name would be systemic herpes simplex.

Within the past few months it has been our unusual opportunity to observe 2 cases of systemic herpes simplex which were proved by animal inoculation and immunization tests to be caused by the virus of herpes simplex. The first case, an extremely severe one, occurred in an adult woman with disseminated chronic neurodermatitis. The second, a mild form of the disease, also occurred in an adult woman; there was no preceding allergic history or dermatitis, but infection followed contact exposure to herpes labialis.

Because these cases represent differences in severity and background of systemic herpes simplex, and because we believe them to be the first cases treated with penicillin and moccasin venom (case 1) and with moccasin venom and diphenhydramine hydrochloride ("benadryl hydrochloride" N. N. R.) (case 2), we report them here.

REPORT OF CASES

Case 1.—*History.*—J. M., a white woman aged 18, employed as a telephone operator, had been treated for several years at the outpatient department of St. Luke's Hospital for a disseminated neurodermatitis.

On March 30, 1946 she was admitted to the dermatology ward suffering from an acute dermatosis of two days' duration. Her statement was that two days before admission she had awakened with a swollen, red, weeping condition of the face accompanied by generalized aching pains. She had stayed in bed and applied hot boric acid compresses to her face. When the swelling increased and blisters spread to other parts of her body, she came to the hospital for treatment.

Further questioning disclosed that four days previous to her cutaneous outbreak, exterminators had sprayed her apartment with a moth preventive. At first, because of her known sensitivity to Pyrethrum, she thought her condition might be the result of the moth spray. Also, it was found that the patient had had a severe head cold, conjunctivitis and general malaise ten days prior to admission. She had not had preceding lesions of herpes simplex, a recent vaccination, nor had she been exposed to persons with either. A few days before admission she had been exposed to measles.

Past History.—The patient had had an allergic dermatitis since infancy. From the age of 14 years this condition had been of the disseminated neurodermatitic type. She had suffered from hay fever from her sixth to her fourteenth year of age. Measles, mumps and chickenpox had occurred in early childhood. (Her mother reported that the attack of chickenpox had been very severe and also said that the patient's maternal aunt had hay fever and her maternal grandmother had asthma.) During the patient's previous visits to the outpatient department, the results of a thorough study in the allergy clinic showed a hypersensitivity to coffee, carrots and Pyrethrum.

Physical Examination.—On admission to St. Luke's dermatology ward, the cutaneous examination revealed redness, edema and swelling of the whole face including the eyelids. There was oozing and crusting on the cheeks with a secondary infection apparent in some of the lesions. The skin on the neck and upper part of the chest, especially on the shoulders, was bright red and moderately edematous. Scattered over the arms, on the flexor surfaces particularly, abdomen and thighs was a patchy chronic neurodermatitis with numerous blood-crusted excoriations. The cervical and submaxillary lymph nodes were enlarged and tender. The rectal temperature was 101 F., and the leukocyte count was 8,200 with 85 per cent polymorphonuclear neutrophils and 15 per cent lymphocytes. The entire condition at first suggested a disseminated neurodermatitis accompanied by an acute contact dermatitis of the face, neck and shoulders or smallpox in its early stages.

Treatment and Course.—On the first evening of hospitalization the patient had a severe chill. Her rectal temperature rose

suddenly to 104 F. and remained between 104 and 105.2 F. for the next three days. Because of the secondary infection of many of the lesions, penicillin was administered; 30,000 units intramuscularly every three hours for five doses. Eighteen hours later, when increased itching and burning of the patient's skin suggested a possible sensitivity, penicillin therapy was temporarily discontinued. Cold boric acid solution compresses were applied to the face and neck

The day after admission the patient was acutely ill. She complained of severe general malaise, and her face showed such pronounced edema, redness and tumefaction that it was swollen beyond recognition. Her eyelids were swollen shut, and vesicles had developed on them as well as on the vermilion border and on the inner side of her lips. Extremely painful lesions in her mouth necessitated tubal feedings and infusions of dextrose and isotonic solution of sodium chloride. A definite conjunctivitis existed, but no vesicles were seen on the cornea or conjunctiva.

On the second hospital day new crops of split-pea-sized vesicles and numerous pustules appeared on the face, neck and chest. A few scattered lesions were evident on the arms, legs and abdomen, as profuse on the normal skin as on the patches of neurodermatitis. Some of the vesicles and pustules had become umbilicated and now looked like the lesions seen in chickenpox. Considerable crusting and secondary infection were present on the face.

Fig. 1 (case 1).—Temperature chart showing daily leukocyte and differential counts and the days on which moccasin venom and penicillin were given. P., polymorphonuclear leukocytes; L., lymphocytes; Lm., mononuclear leukocytes and Eos., eosinophils.

Because of the edema, tumefaction, redness, varicelliform lesions, general malaise, fever and low leukocyte count, a diagnosis of systemic herpes simplex was made.

Penicillin therapy was resumed, 40,000 units being administered every three hours. This dosage was continued for six days until a total of 1,450,000 units had been given. Wet dressings of potassium permanganate solution (1:5,000) were applied to the face and neck for two days.

During the third and fourth days the patient's condition looked grave. Her rectal temperature remained between 104 and 105 F. New groups of varicelliform vesicles and pustules continued to appear on the eyelids, face, neck and upper part of chest, with scattered lesions appearing on the trunk, arms and thighs. Many of the lesions crusted; others ruptured leaving raw, eroded surfaces. By the fourth day the eroded areas were most prevalent on the upper part of the chest and on the shoulders, where they coalesced to form large, irregular-shaped, denuded, granulating patches which bled freely when the dressings were applied. As the secondary infection had now cleared, paste of zinc oxide (with 20 per cent olive oil added) was substituted for the wet dressings of potassium permanganate .

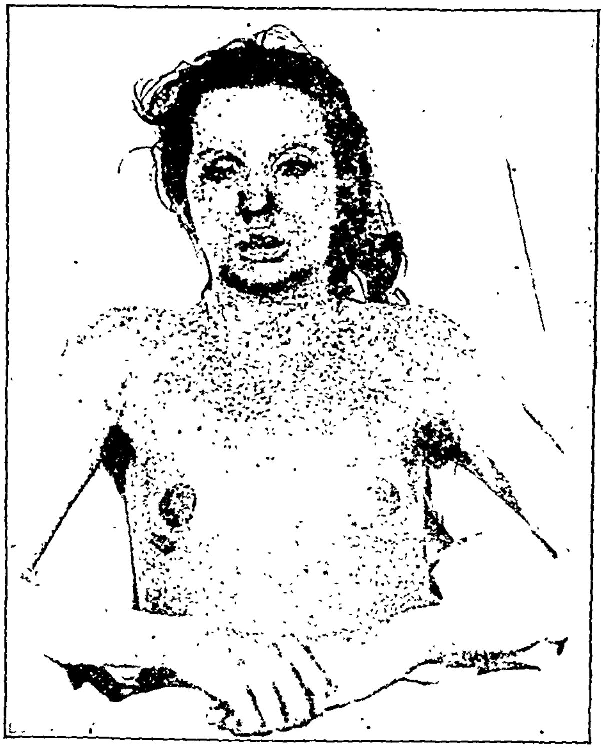

Fig. 3 (case 1).—Photograph on the fourteenth day of the disease, showing crusted lesions *on the chest, neck and eyelids and diffuse redness of the face, neck and chest.*

At this stage, fluid from a vesicle was inoculated into the scarified corneas of two rabbits (the Paul test[17]). This test proved the presence of the virus of herpes simplex.

Because of its reported effect in herpes simplex, 0.1 cc. of moccasin venom[18] (1:3,000 solution) was injected intradermally on the afternoon of the patient's fifth hospital day. Her temperature dropped to 101.4 F. on the following morning but rose again that afternoon to 104 F. A 0.2 cc. dose of snake venom was then administered. The temperature again fell to 100.6 F., but it rose again in the afternoon to 103 F. Another 0.1 cc. of moccasin venom was given, and within six hours the temperature dropped to normal, where it remained except for occasional afternoon elevations to about 100 F. Three subsequent daily injections of the venom, 0.2 cc., 0.3 cc. and 0.4 cc., respectively, were given.

The acute erythema of the face, neck and chest began to subside on the day following the drop in temperature. (Some diffuse redness persisted, however, for four weeks.) Most of the edema, except that on the eyelids, disappeared rapidly. The vesicles and pustules so prominent during the first ten days of the illness continued to appear in decreasing crops until, after the twelfth day, only a few new lesions arose. By the twentieth day all crusts had fallen off leaving red, slightly depressed areas.

The patient's general recovery was simultaneous with her cutaneous improvement. Her diet was gradually increased from fluids to soft solids to a regular diet with the omission of coffee and carrots, to which she was allergic.

When she was last seen, sixty-five days after the onset of her illness, the patient's face and neck still revealed a slight blotchy redness, but no residual scarring was present.

Laboratory Studies.—Daily erythrocyte count and hemoglobin determination were within normal limits throughout the course of illness. The leukocyte count, which was 8,200 on admission, gradually dropped to 3,300 on the sixth and seventh days, then rose again to 8,700 by the thirteenth day (see figure 1 for the differential count).

The Paul test was positive.[17] On the fourth day of hospitalization (sixth day of the disease) fluid from an unruptured vesicle on the chest was inoculated into the right scarified cornea of each of 2 rabbits (R 731 and R 668). Their left corneas were scarified and used as controls. In both rabbits a keratitis developed in twenty-four to forty-eight hours in the inoculated eye, while the control eye healed normally. One rabbit (R 731) died one month later with a severe hemorrhagic diarrhea and acute keratoconjunctivitis. The brain substance from the dead rabbit (R 731) was inoculated into the scarified cornea of a third rabbit (R 760), where it produced a keratitis. A culture of known herpes simplex virus was injected intracerebrally into the surviving rabbit (R 668) of the original pair. This rabbit lived, showing that it had developed an immunity to the virus of herpes simplex.

The patient's blood culture on the second day of hospitalization grew hemolytic Staphylococcus aureus and a hemolytic streptococcus, both of which were thought to be contaminants. A culture of material from an unruptured pustule exhibited the growth of hemolytic Staph. aureus. The sedimentation rate on the third day was 27 mm. per hour (Westergren). Blood urea, sugar, icteric index, total serum protein and nonprotein nitrogen determinations on the first, third and seventh days were all within normal limits. The carbon dioxide combining power of the blood was 40 volumes per cent on the third hospital day. Except for a faint trace of albumin on the first and fifth hospital days, the daily urinalysis revealed normal conditions.

The Wassermann and Kahn reactions of the blood were negative. Roentgenograms of the chest on the third and eighth days revealed normal conditions.

CASE 2.—*History.*—C. C., a white woman aged 35, a private patient, was first seen by one of us (L. P. B.) on May 7, 1946. At that time an eruption consisting of many discrete, slightly elevated, bright red maculopapules was present on her face and neck. Two or three of the lesions were crusted. She also had a typical lesion of herpes simplex on the left side of her lower lip. Her cervical and submaxillary nodes were enlarged, tender and painful. The oral temperature was 100 F., and she complained of general malaise of twenty-four hours' duration. A few days before, she had had a head cold for which she had taken acetylsalicylic acid and phenobarbital. The cutaneous manifestations were suggestive of a drug eruption, chickenpox in the early stage or a diffuse herpetic infection.

Past History.—The patient's past history revealed contact exposures to herpes labialis on April 22, 24, 26 and 30 and on May 3. It was on May 3 that she first noticed a herpetic lesion developing on the left side of her lower lip, and on May 4 a typical cold sore was present on that site. On May 5 two red spots appeared on her chin. By May 6 many red, slightly raised lesions were scattered over her entire face. The cervical and submaxillary lymph nodes had become painful and tender. She suffered from generalized aching pains, and on the evening preceding her visit to the physician's office her oral temperature had risen to 103 F.

There had been no known exposure to chickenpox or vaccinia. As a child, she had had chickenpox and a vaccination for smallpox. Her reaction had not been severe in either instance. No history of cutaneous allergy existed.

The patient was advised to go home to bed, to force fluids, to eat lightly and to apply a modified calamine lotion to her face. That evening her oral temperature arose to 102 F., she had a chill and her general malaise increased. The following day her temperature was 101 F., and the patient was hospitalized.

Physical Examination.—On admission to the hospital the patient was acutely but not seriously ill. The eruption, which was limited to the face and neck, was more profuse than when previously seen and consisted of many discrete, bright red maculopapules about 1 cm. in diameter. Some of these lesions were submounted by a small vesicle and resembled the lesions seen in chickenpox. One lesion had developed on each upper eyelid. There was no diffuse erythema, edema or tumefaction of the face. The throat was slightly injected, and the tonsils were moderately enlarged. No lesions of the mucous membrane were evident other than the original herpes simplex on the lower lip. General physical examination and urinalysis revealed normal conditions. The hemoglobin and erythrocyte count were also within normal limits. The leukocyte count was 7,000 with 60 per cent polymorphonuclear leukocytes, 2 per cent mononuclear leukocytes and 38 per cent lymphocytes.

Because of the varicelliform lesions, fever, general malaise and adenopathy, all of which had followed a herpes simplex lesion that developed after a contact exposure to herpes labialis, a diagnosis of systemic herpes simplex was made.

Treatment and Course of Disease.—Immediately after hospital examination, 0.1 cc. of moccasin venom (1:3,000) was injected intradermally. This dosage was repeated on the second, third and fourth hospital days. A 50 mg. tablet of diphenhydramine hydrochloride was also administered by mouth three times each day for four days. Phenolated lotion of calamine was applied locally, a light diet was prescribed and fluids were forced.

On the morning after admission to the hospital, (fifth day of the disease), the patient's temperature dropped to normal, where it remained thereafter. Her general malaise abated rapidly and the adenopathy subsided within two days. However, small numbers of scattered varicelliform lesions continued to appear singly or in crops of two or three on her face and neck for the next six days, while previous lesions crusted and healed. During the entire course of the eruption only a few lesions became umbilicated.

On the second hospital day fluid from one of the unruptured vesicles was inoculated into a scarified rabbit's cornea, and a typical herpetic keratitis developed.

The patient was discharged after eight days. By that time all but a few of the lesions had healed, leaving small, red macular areas. When the patient was examined ten days later, some redness persisted on the sites of the original lesions but no scarring was evident.

---

[17] The Paul test and rabbit immunization tests (case 1) were done by Margaret Holden, Ph.D., Department of Bacteriology, Columbia University College of Physicians and Surgeons.

[18] Kelley, R. J.: Treatment of Herpes Simplex with Moccasin Venom, Arch. Dermat. & Syph. 38: 599-602 (Oct.) 1938.

COMMENT

Systemic herpes simplex (Kaposi's varicelliform eruption of proved herpes simplex virus origin) may occur in either serious or mild forms which vary mainly in the gravity of the symptoms, extent and severity of the eruption and duration of the illness. The serious form is more likely to attack persons with antecedent dermatoses. Cases 1 and 2 are typical examples of the clinical observations in the severe and mild types, respectively.

Characteristically, the severe form of the disease begins suddenly with general malaise and an abrupt rise in temperature (103 to 105 F.). The temperature remains elevated in a "picket fence" curve for eight to ten days and then falls by lysis or, at times, by crisis. During this period the patients are gravely ill. At the onset the cutaneous eruption is not diagnostic and may be mistaken for dermatitis venenata, atypical chickenpox or smallpox, impetigo contagiosa or a drug eruption. After two or three days the eruption becomes quite typical (see case 1), varying chiefly in extent and severity. At first the lesions appear in crops, then in decreasing numbers for ten to fourteen days. In some cases they may continue to appear for as long as twenty-one days. The vesicles and pustules crust or rupture, usually healing without scar formation. At first, probably due to the secondary infection of the cutaneous lesions, the leukocyte count may be slightly elevated, but after a few days it may drop to 3,000 or 4,000 with a relative lymphocytosis. Some infections are associated with stiff neck, adenopathy, incontinence of the urine and feces, anuria, otitis media, purulent rhinitis, conjunctivitis and corneal ulcers.

In the mild form of systemic herpes simplex the toxemia is not severe and may last no longer than four or five days. The temperature does not rise so high nor is the eruption so extensive. Generally the duration of the milder illness does not exceed a week or ten days.

It is doubtful if treatment alters the course of the disease other than in helping to control secondary infections and complications. In the past, most treatment has been limited to local applications of medicaments. The sulfonamide drugs taken internally have not been beneficial except in 1 case reported by Connor and Gonce in 1943.

Penicillin in case 1 did not influence the patient's illness except in the probable control of secondary infection. Possibly here, as in other virus infections, penicillin therapy is not effective.

After each injection of moccasin venom (case 1) there was a drop in temperature, and there was no further rise after the third injection. However, as the venom was not administered until the seventh day of hospitalization, its efficacy must be considered doubtful. In case 2 when the snake venom was given on the fourth day of the disease the temperature dropped (with no rises thereafter) to normal in twelve hours. These changes in temperature may or may not have been coincidental; hence, we consider that moccasin venom therapy merits further trial.

The effects of diphenhydramine hydrochloride in case 2 are difficult to evaluate because the patient was receiving snake venom simultaneously. All that can be said is that the systemic symptoms disappeared within twelve hours after treatment was begun. We also realize that case 2 was of such a mild type that the disappearance of the symptoms may have occurred in the natural course of the disease.

Our observation of the aforementioned cases leads us to believe that systemic herpes simplex is due to a hematogenous infection as well as to a widespread external inoculation of the virus and that anaphylaxis may play an important role in accounting for its severity.

SUMMARY AND CONCLUSIONS

Two cases of systemic herpes simplex (Kaposi's varicelliform eruption of proved herpes simplex virus origin) in adult women are reported. Case 1 represents the severe form of the disease occurring in a person with a preexisting chronic dermatitis. Case 2 typifies the mild form of the infection appearing in a person with no previous dermatosis after a known contact exposure to herpes labialis.

Results of treatment with penicillin and moccasin venom in case 1 and with moccasin venom and diphenhydramine hydrochloride ("benadryl hydrochloride") in case 2 are equivocal.

The conclusion is drawn that the disease is due to a systemic as well as a widespread cutaneous inoculation of the virus of herpes simplex.

Because of the systemic symptoms and the recovery of the virus of herpes simplex from the cutaneous lesions, the suggestion is made that those cases of Kaposi's varicelliform eruption from which the virus of herpes simplex is recovered, be called systemic herpes simplex.

120 East Seventy-Fifth Street.

Clinical Notes, Suggestions and New Instruments

TUBERCULOUS MENINGITIS AND MILIARY TUBERCULOSIS ARRESTED WITH STREPTOMYCIN

EMANUEL APPELBAUM, M.D.
and
CYRILLE HALKIN, M.D.
New York

Several investigators have shown that streptomycin possesses the ability to suppress a tuberculous process. However, the use of this antibiotic in tuberculous meningitis has resulted in most instances either in failure of response or in an unsatisfactory arrest of the disease, complicated by serious neurologic sequelae. Therefore it seems worth while to report a case of tuberculous meningitis associated with generalized miliary tuberculosis, in which complete clinical arrest followed the use of streptomycin.

REPORT OF CASE

T. E., a boy aged 9, was admitted to the Willard Parker Hospital on Sept. 1, 1946, with the complaints of fever, headache and vomiting of one week's duration. Two days before admission the child became somewhat disoriented. The past history revealed that in November 1945 the disease of the child was diagnosed as miliary tuberculosis of both lungs. The family history was relevant, since the patient's father died of pulmonary tuberculosis in 1944.

From the Bureau of Laboratories, New York City Health Department, and the Willard Parker Hospital.

We wish to express our gratitude to Miss Ruth Gosling and Mrs. Carolyn R. Falk of the Bureau of Laboratories, New York City Health Department, for valuable laboratory assistance, to Dr. Vera B. Dolgopol, Pathologist, Willard Parker Hospital, for the guinea pig necropsy studies, and to Dr. Edwin P. Kolb of the Suffolk Sanatorium for permission to use his data on the case.

Physical examination revealed a thin child who appeared chronically ill. The temperature was 103 F., the pulse rate 98 and the respiratory rate 26. The pharynx was moderately injected and showed evidence of a postnasal drip. There was a generalized lymphadenopathy. Over the right lung resonance was somewhat diminished and the breath sounds appeared harsh. Examination of the heart revealed no abnormalities. The abdomen was moderately spastic on the right side but was not tender. The spleen was not palpable. There was pronounced nuchal rigidity associated with positive Brudzinski and Kernig signs. The deep and superficial reflexes were active, and no pathologic reflexes were elicited. The child's mental state was clear.

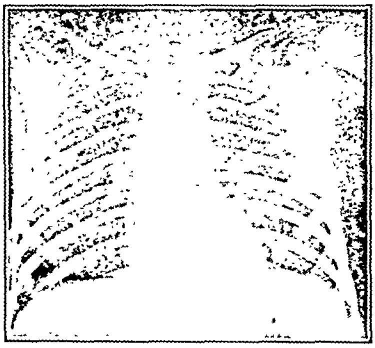

Fig. 1.—Roentgenogram of the lungs taken shortly after admission. Note hilar gland enlargement and extensive miliary infiltrations.

Urinalysis revealed a trace of albumin, an occasional hyaline cast and 8 to 10 white blood cells. The red blood cell count was 4,700,000, with 70 per cent hemoglobin; the white blood ount was 8,500, with 78 per cent polymorphonuclear leukocytes, 0 per cent lymphocytes and 2 per cent monocytes. The spinal fluid on September 3 was clear, with 295 cells, predominantly mononuclears; 84 mg. of protein and 39 mg. of sugar, per hundred cubic centimeters, and no organisms by smear or culture. However, Mycobacterium tuberculosis were found by smear and culture in the second specimen of spinal fluid obtained on September 5. A roentgenogram of the chest disclosed hilar gland enlargement and extensive miliary infiltrations of both lungs (fig. 1). A diagnosis of tuberculous meningitis and miliary tuberculosis was thus established.

On the fourth day after admission the child's condition became decidedly worse, evidenced by pronounced irritability, apathy, grinding of the teeth and carphologia. Streptomycin therapy was instituted on Sept. 6, 1946. The child received 200,000 units of the antibiotic intrathecally once a day. In addition 100,000 units were injected intramuscularly every three hours. Except for an occasional minor change, this scheme of dosage was maintained for twenty-six days.

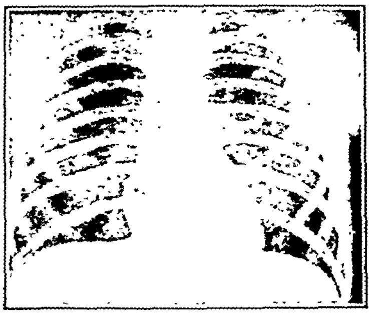

Fig. 2.—Roentgenogram of the lungs taken Jan. 11, 1947, after four months of streptomycin therapy. Except for a small residual focus in the left lung there is complete clearing of the infiltrations.

On September 8, two days after the streptomycin treatment was started, there was a striking improvement in the mental state. However, the signs of meningeal irritation persisted and an irregularly septic type of fever, ranging between 99 and 103 F., continued. The observations in the lungs, clinical and radiographic, also remained unchanged.

The child continued to improve, developed a sense of well-being and gained weight. On October 2, twenty-seven days after treatment was started, the intrathecal administration of streptomycin was discontinued. At the same time the systemic use of the drug was increased to 1,000,000 units daily and administered for five days by continuous intramuscular infusion and subsequently by interrupted injections. The temperature became low grade in type. Repeated roentgenograms of the chest, however, disclosed little change.

On October 9 the child again appeared drowsy and irritable. Two hundred thousand units of streptomycin were therefore injected intraspinally. Since the temperature rose to 101.4 F. following this treatment, it was decided to abandon the use of the drug intrathecally but to continue the intramuscular therapy.

Clinical improvement was soon in evidence again. Particularly striking were the child's alertness and playfulness. The roentgenogram of the chest also disclosed a slight clearing. In an attempt to accelerate the pulmonary improvement the daily dose of systemic streptomycin was increased on October 18 to 2,000,000 units. This dosage was continued for twelve days.

On October 31 the patient was transferred to another institution, where the intramuscular injections of streptomycin were continued for approximately four months. There was one short interruption of three days, when the injection of the drug was omitted because of the development of a transitory rash and dizziness. The daily dosage of streptomycin from

Nov. 1, 1946 to Feb. 28, 1947 varied from 600,000 to 1,600,000 units. Under this regimen there was well defined and progressive improvement. The child gained weight, was active and playful and appeared normal in all respects. A roentgenogram on Jan. 11, 1947 showed complete clearing of the miliary tuberculosis and only a small residual focus in the left lung (fig. 2).

As will be noted in the accompanying table, the fourth specimen of spinal fluid, obtained on Sept. 7, 1946, as well as all subsequent specimens, did not show the presence of organisms by smear or culture and had a normal sugar content. On the other hand, the elevated protein and decided pleocytosis persisted.

There were some other laboratory data worthy of note. Several specimens of urine obtained during the course of therapy showed a moderate amount of albumin and an occasional hyaline and granular cast. The streptomycin sensitivity of the Myco. tuberculosis isolated from the spinal fluid was 0.095 units per cubic centimeter. Frequent determinations were made on the concentrations of streptomycin in the blood and spinal fluid. The blood levels of the drug ranged between 1 and 31 units and the spinal fluid levels between 1 and 16 units per cubic centimeter. Tuberculin-negative guinea pigs inoculated with the spinal fluid culture subsequently became tuberculin-positive and died one month after the inoculation. At necropsy extensive tuberculous lesions, including the presence of Myco. tuberculosis, were found in the spleen, liver, lymph nodes and subcutaneous tissue.

A follow-up on May 23, 1947, approximately nine months after the onset of his illness, found the patient in excellent condition. The child was free of symptoms and appeared normal physically and mentally.

COMMENT

In this case the diagnosis of tuberculous meningitis was established by the clinical observations and confirmed by the spinal fluid studies. In addition, the roentgenogram revealed the presence of pulmonary miliary tuberculosis. The results of the guinea pig inoculations furnished absolute proof that the organisms isolated from the spinal fluid were virulent Myco. tuberculosis.

It has become known that the use of streptomycin in tuberculous meningitis may produce temporary improvement and on infrequent occasions lead to an arrest of the disease. However, most of the cases in the latter group have shown serious neurologic residua. In the case reported herein the disease was arrested completely without any sequelae. It is likely that this excellent result was due in no small measure to certain favorable factors, such as the institution of the streptomycin therapy early in the disease, the pronounced sensitivity of the organism to the drug and the adequate concentrations of the antibiotic in the blood and spinal fluid.

It is also of interest to note that the streptomycin was well tolerated by our patient during the long course of treatment. Except for one short episode of dizziness and the occurrence of a transitory rash, there were no serious untoward reactions. Because of the presence of albuminuria and cylindruria before the initiation of streptomycin therapy it is difficult to evaluate the significance of these urinary observations in subsequent specimens. However, as pointed out by Farrington and associates,[1] the development of cylindruria without other evidence of renal disease is not in itself a reaction of serious significance.

The persistence of the elevated protein level and of the pleocytosis in the spinal fluid was undoubtedly due to the intrathecal administration of the streptomycin. Unfortunately, a spinal tap was not performed late in the convalescence to recheck these determinations.

SUMMARY

In a case of tuberculous meningitis associated with miliary tuberculosis complete clinical arrest followed a long and intensive course of streptomycin therapy. The drug was well tolerated, and there were no neurologic residua.

STREPTOMYCIN IN TUBERCULOUS MENINGITIS

C. P. MEHAS, M.D.
and
WAYNE E. TRUAX, M.D.
Pontiac, Mich.

Tuberculous meningitis has always carried a hopeless prognosis. The use of streptomycin in the treatment of this disease has already altered the outlook. Waksman and his associates[1] reported the isolation of a new antibiotic agent in 1944. Feldman and Hinshaw reported in 1944[2] its apparent ability to suppress the growth of Mycobacterium tuberculosis in guinea pigs. Since that time several reports in the literature have confirmed the bacteriostatic action of streptomycin on Myco. tuberculosis. Its first successful use in tuberculous meningitis was reported by Cooke, Dumphy and Blake,[3] who treated an infant 1 year of age. Krafchik[4] reported another apparent arrest in a child 5 months of age, significant in that no residual neural damage was noted. Recently Hinshaw, Feldman and Pfeutze[5] reported a series of 9 cases of combined miliary and meningeal tuberculosis in 4 of which the patients survived. In all their successful cases the patients were treated by intramuscular administration of 1 to 3 Gm. of streptomycin daily, combined with the intrathecal administration of 100 to 300 mg. of the agent every twenty-four hours. The importance of concurrent intrathecal administration with intramuscular administration of the drug has been emphasized by Hinshaw and his group. They state, "None of the cases who died had received intrathecal therapy, and none of those who received intrathecal therapy have thus far died."[5] Of the 4 patients surviving in their series, 1 is blind, 1 has pronounced cerebellar symptoms, 1 is deaf and 1 is normal. They consider that the deafness may be due to streptomycin. This particular toxic effect of the drug has been noted by almost all who have used it over long periods.[6] Vertigo and tinnitus are often accompaniments of the deafness. Fowler[6a] has shown that damage is not always permanent and that return to normal may be expected in many instances after stopping the administration of the drug.

We know that there are numerous cases of tuberculous meningitis being treated throughout the country which have not, as yet, been reported but will be very soon. We offer this case report concerning an adult patient with tuberculous meningitis and pulmonary tuberculosis whom we treated with streptomycin in the hope that our experience may be of some assistance in treatment now in progress. We consider that this case shows not only that streptomycin may alter the course of tuberculous meningitis but also that intrathecal administration alone, though not sufficient to totally suppress the disease, can suppress it for a prolonged period, in this case, without producing a resistant strain of the organism. While definite allergic and toxic effects of the drug are demonstrated, the possibility that these changes may not be permanent is also shown.

REPORT OF CASE

History.—Mrs. F. A., a white woman aged 31, was admitted to the Oakland County Tuberculosis Sanatorium July 3, 1946, complaining of pleuritic pain in the lower part of the left lung of five months' duration. She also had fever, night sweats, a productive cough and a loss of weight of 15 pounds (7 Kg.).

From the Oakland County Tuberculosis Sanatorium.

Acknowledgment is due to Karl H. Pfeutze, M.D., Cannon Falls, Minn., for invaluable advice.

One month before admission she had been hospitalized elsewhere and a left pleural effusion had been aspirated. She was told that she had tuberculosis. The history was essentially negative except for painful menses, heavy flow and temperature elevation during menses.

Physical Examination.—The patient was a well developed white woman who had no significant physical abnormalities except for flatness to percussion with absent breath and voice sounds over the base of the left lung. Pelvic examination revealed an anteverted uterus with profuse yellowish white cervical discharge, which proved to be nonspecific.

Laboratory Data.—Roentgen Examination: In the right lung a mottled type of infiltration was noted in the first interspace anteriorly extending up to the apex. This was extremely suggestive of an active exudative tuberculosis. In the left lung a concave opacity was observed to extend out from the hilum to the base and up to the eighth rib posteriorly, contributing to a definite obliteration of the costophrenic angle.

Summary: This was apparently a case of bilateral pulmonary tuberculosis complicated by pleural effusion on the left.

Hematologic Study: The hemoglobin level was 78 per cent. The red blood cell count was 4,010,000; the white count 6,050, with 60 per cent polymorphonuclears; 34 per cent lymphocytes; 3 per cent monocytes, and 3 per cent eosinophils. The color index was 0.9. Urinalysis was negative; the Kahn test was negative; the sedimentation rate was 51 mm. in one hour (Westergren). The sputum culture was positive for acid-fast bacilli.

Course in Hospital.—The patient was placed on a strict regimen of rest in bed and a repeat roentgenogram of the chest was taken in six weeks. This showed slight resolution of the pleural effusion on the left. There was essentially no change on the right. The case was presented at a surgical conference, and a temporary left phrenic crush was thought to be the procedure of choice. However, on September 19, forty-eight hours before planned surgical intervention, the patient began to complain of indefinite pain in the lower part of the abdomen, associated with severe headache and nausea. Forty-eight hours later definite nuchal rigidity developed, accompanied by an elevation of the temperature to 103 F., vomiting, nausea, mental confusion and hyperactive reflexes. A lumbar puncture at this time revealed an increase in the cerebrospinal fluid pressure. The fluid was clear, with a cell count of 29 (lymphocytes predominating), a globulin reading of 2 plus and a normal sugar determination.

A tentative diagnosis of tuberculous meningitis was made. On October 2 another lumbar puncture revealed the fluid to be cloudy; the cell count was 236 with polymorphonuclear cells predominating, globulin 3 plus and sugar absent. A well developed pellicle which formed on the fluid on standing revealed typical acid-fast bacilli on direct smear. The cultural characteristics on mediums and the pathologic changes in the guinea pig which this specimen ultimately revealed were typical of Myco. tuberculosis. During this interval the patient continued to regress rapidly with clearly marked symptoms of tuberculous meningitis. On October 3 a small supply of streptomycin was made available,[7] and daily intrathecal administration of 200 to 250 mg. was begun with the intention of giving additional intramuscular injections of the drug when it became available. Within a few days after the starting of streptomycin therapy the patient began to show clinical improvement with clearing of stupor and lessening of meningismus. However, vomiting continued, and it was necessary to administer intravenous amino acids and dextrose to sustain nutrition and fluids until the patient could increase her own intake. Meanwhile, because of the difficulties encountered in obtaining streptomycin we were forced to use intraspinal administration alone of 250 to 300 mg. daily for a total period of forty-three days. During this interval, cells in the spinal fluid had risen rapidly to 1,044 with lymphocytes predominating on the tenth day of treatment (see the accompanying table) and then gradually receded to 54 cells on the twenty-third day, at which time the globulin was positive, the sugar reaching 44.5 mg. per hundred cubic centimeters. On the twenty-fourth day of treatment the cell count gradually started to rise. By the forty-third day the count had reached 491 cells and a web formed on standing; the sugar, however, remained normal. The patient's clinical condition began to retrogress rapidly with spiking temperatures, stupor, pronounced muscular rigidity and headache. Fortunately at this time an adequate supply of the drug was made available and intramuscular streptomycin, 2 Gm. daily, was begun. In forty-eight hours clinical symptoms of meningitis began to disappear and the patient was greatly improved mentally with disappearance of neurologic symptoms. Along with the intramuscular dosage the intrathecal administration of the drug was continued, with 300 mg. given every other day. The intrathecal injections continued without incident until January 10, when it was observed that the patient's temperature was 103 F. and she became stuporous and mentally confused after a spinal injection. This occurred with each spinal injection and was considered to be a toxic reaction due to direct stimulation by streptomycin on the central nervous system, and the intraspinal administration of the drug was stopped. The patient became completely afebrile

Cerebrospinal Observations and Streptomycin Therapy

7. William A. Hudson, M.D., Detroit, provided the first supply of streptomycin.

thereafter. Another toxic or allergic reaction noted was the gradual increase in eosinophils in the peripheral blood, rising from a level of 3 to 6 per cent to a decided elevation of 22 per cent on February 14. At the peak of this eosinophilia the patient had one generalized convulsion lasting five minutes, typically epileptiform in type. The drug was not discontinued, however, and the eosinophilia gradually subsided to normal. Administration of the drug was stopped on March 25 because of local reaction to the intramuscular injection marked by a localized induration, swelling and pain at the site. During the last two months of therapy definite objective impairment of hearing, more pronounced on the left, was noticed by the patient and by observers. Audiograms taken one week after the cessation of therapy, on April 2, 1947, and six weeks later, on May 27, 1947, revealed the following:[8]

The tympanic membranes were of normal appearance. Both eustachian tubes were patent. The tuning fork test of Weber was lateralized to the right. With the Rinne test, bone conduction was greater than air conduction on both the right and the left. The Schwabach test showed decidedly reduced times on the left and reduced times on the right. The 2048 tuning fork air conduction on the left was greatly reduced, and on the right, reduced.

The conclusion was that the patient presented a definite perceptive hearing loss, especially in the left ear. The audiogram revealed 19.3 per cent loss in the right ear and 89.8 per cent in the left ear on April 2, 1947. On May 27, 1947 the right ear revealed a hearing loss of 13.8 per cent and the left ear 71.0 per cent. This was a definite improvement in hearing over the audiogram of April 2, 1947.

For the first few weeks after starting the patient on exercise there was noted a definite ataxic steppage gait with obvious equilibrial disturbance. The Romberg sign was definitely positive, the patient falling to the right. There had been no adiadokokinesis or difficulty in performing the finger to nose test or past pointing. Now, three months after the cessation of treatment the gait is nearly normal, the Romberg sign is still slightly positive, and equilibrium has decidedly improved so that the patient can walk to the bathroom unassisted. Besides the definite neural involvement on the left, as already noted, the other residual damage to the central nervous system is indicated by a lateral nystagmus on the left.

At the present time the spinal fluid values are within nearly normal limits, with 6 to 9 cells, a total protein level of 50.6 mg. and sugar 55 to 60 mg. per hundred cubic centimeters. Positive cultures had not been obtained since the start of streptomycin therapy.

The pulmonary status of the patient must be mentioned. Sputum cultures became negative two months after treatment began. The pleural effusion on the left has now completely absorbed and the infiltration on the right has cleared and stabilized. The total period of treatment was one hundred and seventy-five days, and 282 Gm. of streptomycin were given. Seventy-one spinal punctures were performed.

COMMENT

The prognosis of tuberculous meningitis has been a hopeless one until the advent of streptomycin. The value of this drug in altering the course of this disease has been previously shown in 2 children and in 4 adults coincidentally affected with miliary tuberculosis. A case is reported of proved tuberculous meningitis in an adult female with no evidence of miliary disease whose course of disease has been significantly altered by the use of streptomycin, both intramuscularly and intraspinally administered. It illustrates the importance of early diagnosis and treatment. It also demonstrates that intraspinal (thecal) streptomycin alone, though insufficient to completely halt the progress of the disease, can suppress the disease for a significant period without, in this case, producing a resistant strain of the organism. Certain toxic effects of the drug are illustrated, these being primarily due to its effect on the central nervous system.

CONCLUSION

Streptomycin administered early in the course of tuberculous meningitis is capable of arresting the process.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

The Council has authorized publication of the following statement.

Austin Smith, *Secretary.*

SULFONAMIDES FOR LOCAL APPLICATION DELETED FROM N. N. R.

Nearly two years ago the Council on Pharmacy and Chemistry published a report on the "Dangers from External Use of Sulfonamides,"[1] citing the evidence then available that the promiscuous use of these drugs in the form of ointments, lotions, powders and other preparations suitable for local application resulted in the sensitization to these drugs of a high proportion of those treated. Since that time, evidence has continued to accumulate confirming the views then expressed that the local application of these drugs should be limited to the relatively few cutaneous infections known to respond to this form of therapy and that such medication should be administered only under the careful supervision of a physician. Recently Lyons[2] has emphasized the reasons for abandoning the local use of the sulfonamides in treating wound infections, citing the experience gained in World War II which showed that these drugs delayed healing and were otherwise definitely deleterious, and furthermore that these drugs were ineffective for the purpose for which they were used, namely, wound sterilization.

In dermatologic practice it has been found that systemic therapy, preferably with an antibiotic such as penicillin, or local therapy with antibacterial agents less prone to produce sensitivity, will effectively control most cutaneous infections formerly treated with sulfonamides and in general is more effective and far less hazardous to the patient. In view of these facts the Council voted to delete from the 1947 edition of N. N. R. the discussion on the local use of the sulfonamides and to substitute the following statement: "Experience gained in World War II seems to indicate that the use of crystalline sulfonamides as topical agents was not very successful in the management of wound infection or in treatment of infections of the skin or mucous membrane. The routine use of sulfonamides as topical applications in wounds, burns and in superficial infections is therefore to be discouraged."

During its consideration of the foregoing statement the Council consulted thirty-six physicians representing the leading authorities in several branches of medicine in which sulfonamide therapy might be widely used. The consensus clearly revealed that there was no need for continuing in New and Nonofficial Remedies sulfonamides intended for topical therapy. As a consequence, the acceptance of such preparations has been rescinded and the firms concerned have been notified of this action.

Pertinent also is the resolution adopted by the Section on Dermatology and Syphilology of the American Medical Association at its 1944 session condemning the indiscriminate local use of sulfonamides in diseases in which other ordinarily less harmful remedies are equally efficacious.[3] The American Dermatological Association has also adopted a similar resolution.

The Council believes it necessary to emphasize again the potential hazards of the indiscriminate topical use of sulfonamide preparations. Inquiries are being received concerning the local use of sulfonamides in conditions for which there is no evidence of their value, such as hair tonics to control dandruff and promote growth of new hair, in shave creams to prevent infection, and in other equally inconsequential preparations. Not only are the sulfonamides ineffective in such preparations, but their use in any concentration represents a real danger to the user for three reasons: (1) the substitution of an ineffective remedy for one which might be of value, (2) the possibility, now widely recognized, of permitting the development of sulfonamide resistant organisms and (3) the development of cutaneous sensitization, thus preventing the use of sulfonamides in serious conditions for which these drugs are known to be effective.

---

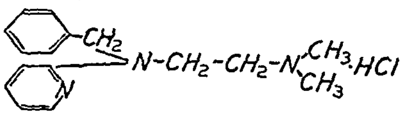
TRIPELENNAMINE HYDROCHLORIDE.

—Pyribenzamine Hydrochloride-Ciba. — N,N-dimethyl-N′-benzyl-N′-(α-pyridyl) ethylenediamine hydrochloride. — Beta-dimethylaminoethyl-2-pyridyl-benzyl ammonium chloride.—$C_{16}H_{22}N_3Cl$.—*M. W. 291.84.* The structural formula of tripelennamine hydrochloride may be represented as follows:



Actions and Uses.—Tripelennamine has the capacity to antagonize many of the pharmacologic effects of histamine. It prevents histamine-induced spasm of smooth muscle and it protects guinea pigs exposed to inhalation of nebulized histamine. Tripelennamine provides adequate protection to guinea pigs injected intravenously with lethal doses of histamine. If administered prophylactically to sensitized guinea pigs, it prevents anaphylaxis to subsequent injections of antigen.

Tripelennamine has been found useful in the treatment of urticaria or seasonal allergic rhinitis and appears to be useful in treating about half of those patients suffering from nonseasonal allergic rhinitis and bronchial asthma. It may also be useful in other allergic disorders, but greater clinical experience necessary before its precise role in the treatment of these conditions can be determined.

Tripelennamine does not affect the underlying allergic state, and therefore cessation of medication while the patient is still exposed to the allergen usually results in a prompt return of symptoms.

Approximately 30 per cent of patients experience side effects of varying degrees of severity following medication with tripelennamine. The most frequent side effect is that of drowsiness. It is important, therefore, to observe caution in administering sedatives or hypnotics to persons under treatment with this drug. Other reactions which have been observed are nausea, headache, dizziness, dryness of the mouth, nervousness and occasionally abdominal discomfort.

Dosage.—The smallest dose which will control the symptoms should be used. Treatment may be started with 50 mg. by mouth four times daily, preferably after meals. If symptoms are controlled, the dosage is reduced to 50 mg. twice daily or 25 mg. four times daily. Lower doses may be adequate. If symptoms are not controlled, and in the absence of side effects, the dosage may be increased to 100 or 150 mg. four times daily.

Tests and Standards.—

Tripelennamine hydrochloride occurs as a white crystalline powder possessing a bitter taste. It melts in the range 189-192.5 C. It is very soluble in water, soluble in alcohol and in chloroform, and practically insoluble in benzene and in ether. The *pH* of a 10 per cent solution is from 6.4 to 6.6.

Acidify 2 cc. of a 1 per cent solution of tripelennamine hydrochloride with 2 drops of nitric acid. Add 5 drops of silver nitrate solution: a white precipitate develops, which is redissolved on the addition of a few drops of ammonium hyroxide.

Add 3 drops of saturated Reinecke's salt solution to 2 cc. of a 1 per cent aqueous solution of tripelennamine hydrochloride: a flocculent, pink precipitate develops.

Prepare the dipicrate of tripelennamine as described in the assay: the tripelennamine dipicrate melts at 185-190 C.

Add 3 cc. of sulfuric acid to 0.1 Gm. of tripelennamine hydrochloride: a yellow color develops which turns muddy brown with a definite greenish cast on standing (*distinction from benadryl hydrochloride*).

Dry 0.2 Gm. of tripelennamine hydrochloride, accurately weighed, in vacuum over phosphorus pentoxide at room temperature for twenty-four hours: the loss in weight does not exceed 0.5 per cent.

Ash about 0.2 Gm. of tripelennamine hydrochloride, accurately weighed: the amount of residue is not more than 0.3 per cent.

Weigh, accurately, about 100 mg. of tripelennamine hydrdochloride and transfer to a 100 cc. beaker. Dissolve the salt in 50 cc. of water to which 4 drops of sulfuric acid has been added and add slowly, while stirring, 25 cc. of a filtered saturated solution of picric acid. Allow the mixture to stand for two hours, filter through a tared Gooch crucible, dry at 100 C. for two hours, cool and weigh. Each gram of tripelennamine dipicrate is equivalent to 0.40896 Gm. of tripelennamine hydrochloride: the tripelennamine hydrochloride content is not less than 98 per cent nor more than 102 per cent.

Tripelennamine Hydrochloride Tablets

Weigh ten tablets and grind in a mortar. Extract about 100 mg. of the powdered tablet mixture with two 25 cc. portions of chloroform. Centrifuge, decant the chloroform solution of tripelennamine hydrochloride and evaporate to dryness on a steam bath: the resulting crystals melt at 185-191.5 C.

Weigh, accurately, about 0.4 Gm. of the pulverized tablets and suspend in 25 cc. of water containing 2 drops of sulfuric acid in a 50 cc. centrifuge tube. Set the suspension aside for about fifteen minutes, stirring frequently. Centrifuge for about ten minutes; then decant the aqueous layer into a 100 cc. beaker. Add 25 cc. of water containing 2 drops of sulfuric acid to the residue in the centrifuge tube. Stir and mix thoroughly, set the suspension aside for fifteen minutes, stirring frequently, and again centrifuge. Add the supernatant liquid to the first extract in the 100 cc. beaker. Repeat the extraction for a third time as described previously and add the supernatant liquid to the other extracts. Add slowly to the combined extracts, while stirring, 25 cc. of a filtered saturated aqueous picric acid solution. Let the suspension stand for two hours, filter on a tared Gooch crucible, dry at 100 C. for two hours, cool and weigh. Each gram of tripelennamine dipicrate is equivalent to 0.40896 Gm. of tripelennamine hydrochloride: the tripelennamine hydrochloride content is not less than 95 per cent nor more than 105 per cent.

Ciba Pharmaceutical Products, Inc., Summit, N. J.

Tablets Pyribenzamine Hydrochloride: 50 *mg.*

U. S. patent 2,406,594.

SUSPENSION OF EPINEPHRINE IN OIL 1:500

(See New and Nonofficial Remedies, 1946, p. 296).

The following dosage form has been accepted:

Winthrop Chemical Co., Inc., New York

Suprarenin in Oil 1:500: 1 cc. ampuls. Each cubic centimeter contains 2 mg. Suprarenin (base) in sesame oil.

Council on Physical Medicine

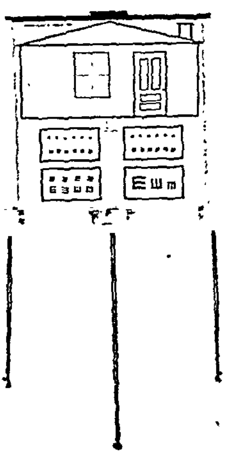
The Council on Physical Medicine has authorized publication of the following report.

Howard A. Carter, *Secretary.*

MASSACHUSETTS VISION TEST ACCEPTABLE

Distributor: Welch Allyn Company, Auburn, N. Y.

The Massachusetts Vision Test developed by the Division of Child Hygiene, Massachusetts Department of Public Health, is designed to simplify screening examinations of the eyes of school children especially in the primary grades. This form of the Massachusetts Vision Test supersedes the form whose acceptance by the Council was reported in The Journal of the American Medical Association May 1, 1943.



Massachusetts Vision Test

The redesigned instrument consists of screening tests for far and near vision, vertical and horizontal muscle balance for distance and near and hyperopic astigmatic errors. The carrying case, 29 by 7½ by 5¼ inches (74 by 19 by 13 cm.) also serves as a stand for the test charts and as a container for the muscle and near vision tests.

In a clinic acceptable to the Council the instrument was used experimentally for a period of one month. The Massachusetts Vision Test was found to be constructed on sound optical and physiologic principles and the mechanical construction was sturdy. Its successful use requires preferably a person experienced in the handling of children as well as in visual testing.

The Council on Physical Medicine voted to include the Massachusetts Vision Test in its list of accepted devices.

DISINFECTAIRE—WITHDRAWAL OF ACCEPTANCE

Manufacturer: The Art Metal Company, 1814 East 40th Street, Cleveland.

In The Journal, Jan. 15, 1944 "Disinfectaire-Ultraviolet Germicidal Units" were accepted. These lamps were accepted for disinfecting the air in hospitals, baby cubicles and operating rooms. The acceptance was limited to these installations.

An envelope stuffer entitled "Purify the Air You Breathe with Electronic Air Disinfection—Install Disinfectaire" came to the attention of the Council In the opinion of the Council the folder contained misleading claims. In the advertisement the lamp was recommended for installation in homes, schools, factories, stores, offices, theaters, restaurants and cafeterias. In view of the evidence coming to its attention the Council was not convinced that the disinfecting ultraviolet lamps are of significant value in the aforementioned installations.

The Art Metal Company was informed of the objectionable advertising matter. The firm replied, in part, "We believe that the weight of data obtained from practical field experience adequately supports any claims that we may make concerning our products." The firm further stated that ". . . we see no reason to alter the advertising and promotional material."

The Council on Physical Medicine after due consideration voted to withdraw the Disinfectaire Ultraviolet Germicidal Units from its list of accepted devices.

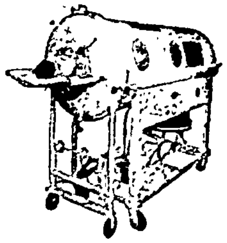
FABRIKATOR RESPIRATOR ACCEPTABLE

Manufacturer: Fabrikators Inc., of Mass., 19 Walnut Street, Boston 32, Mass.

The Fabrikator respirator is a device designed to produce artificial respiration simulating natural breathing. It accommodates either 1 adult only or 2 children at the same time.

Description: The apparatus functions by alternately producing suction (subatmospheric) and atmospheric pressure in the chamber. The lungs are inflated during suction and passively deflated during the atmospheric phase of pressure. Positive pressure may be used to assist exhalation The number of respirations per minute ranges approximately from fourteen to twenty-eight and any point between these settings.

The unit consists of a cylindric steel chamber mounted on a welded steel framework, which also supports the operating mechanism. The chamber contains a cot attached to the removable end closure. Casters on the legs of this closure and on the cot facilitate rolling the cot from the chamber and tilting the chamber. The respirator is 58 inches high, 85 inches long and 29 inches wide (internal chamber diameter of 25¾ inches throughout) and the shipping weight is 700 pounds. The respirator is mounted on casters so that it can be moved conveniently.



Fabrikator Respirator

There are five regulation arm pits, one bed pan, four observation windows in the chamber and internal lighting. Easily closed covers seal the openings when not in use. Other features are the "spiralock" collar adjustment apparatus, a rubber covered mattress, a cot elevating handwheel and an adjustable head rest. For tilting in cases in which postural drainage is desired there is a hydraulic jack at one end.

A ¼ horse power motor drives a gear reduction unit controlling the opening and closing of the multicorrugated U. S. rubber bellows. The bellows can be operated by hand. A control panel is mounted on the side of the respirator and bears switches for the motor and light, and handles for negative and positive pressure. A gage indicates the internal pressure in centimeters of water.

This apparatus was investigated in a clinic acceptable to the Council. It was found to be a substantial piece of equipment. The report is summarized as follows:

1. It can be used for 2 child patients at the same time, or by 1 adult by the simple expedient of closing off the end which is not being used by the patient.
2. The head rest sling is adjustable.
3. The spiralock collar simplifies placing the patient's head through the rubber seal-off because the opening in the collar is adjustable.
4. A hydraulic jack makes the tilting of the respirator, such as would be needed for bulbar cases, a simple procedure.
5. Mechanisms are included which make possible rotation of the patient from side to side without opening the respirator.
6. The head end of the cot can be raised readily by means of a hand wheel.

The Council warned that the spiralock collar itself, while very efficient, is of stiff rubber, and a careless nurse might easily strangle a patient when she closes the collar opening.

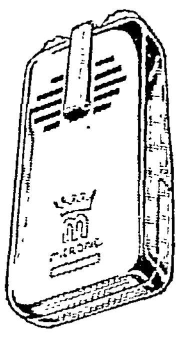
The Council on Physical Medicine voted to include the Fabrikator Respirator in its list of accepted devices.

SILVER MICRONIC HEARING AID MODEL 101 ACCEPTABLE

Manufacturer: Micronic Corporation, 101 Tremont Street, Boston 8.

This instrument is self contained, the battery compartment being accessible from the back of the case. The wearing clip is on the back of the aluminum case. The receiver cord plugs into the unit inside the battery case, with the cord leaving the case through a rubber grommet.

The volume control and the on-off tone switch are placed at the top of the instrument. One crystal receiver was supplied with the instrument.



Silver Micronic Hearing Aid Model 101

Dimensions and Weight

Dimensions: 10.5 by 5.7 by 2.6 cm.

Weight: 170 Gm.

Battery Data

	Measured	
	Voltage	Current
A:	1.3 volts	46 milliamperes
B: No sound	22 volts	0.5 milliampere
Squealing	22 volts	0.35 milliampere

Acoustical Gain

Measurements were made of the acoustical gain in decibels (sound pressure level produced in a 2 cm. coupler in decibels above sound pressure at the face of the microphone set in a 16 by 8 inch baffle). The input level was held constant at each frequency corresponding to 0.02 dynes per square centimeter or equivalent to a level of 40 decibels above 0.0002 dynes per square centimeter.

Typical results, with the volume control full on, were tabulated as follows:

Frequency	256	512	1,024	1,200	2,250	3,100	4,096 cycles per second
Tone control:							
1 dot	34	40	49	56	36	36	49 decibels
2 dots	14	25	39	45	24	25	35 decibels

Approximate values of maximum pressure levels at four frequencies produced in a 2 cm. coupler with the volume control set for full gain and at 1 dot tone setting are as follows:

Frequency	Input Level	Maximum Output Level
600 cycles	60 db.	100 db.
1,024 cycles	65 db.	105 db.
1,200 cycles	65 db.	111 db.
2,048 cycles	65 db.	93 db.

Intelligibility tests were made with a hard of hearing subject. The articulation and whispering tests were satisfactory, giving 90 per cent scores.

The Council on Physical Medicine voted to accept the Silver Micronic Hearing Aid, Model 101, for inclusion in its list of accepted devices.

SATURDAY, SEPTEMBER 20, 1947

THE PHYSICIAN AND THE SCHOOL

Each year thousands of physicians serve our schools in varying capacities. In many communities they serve only as part-time medical inspectors who give medical examination to children entering school in the fall without medical examination by the family physician. In other communities the physicians are specially trained in school health service and are employed as full-time school medical advisers to work with pupils, teachers and administrators in carrying out a planned program of educational and preventive medical services and health guidance throughout the year. In other less fortunate communities little if any physician's service is provided in the school; only in epidemics of measles, scarlet fever, food-poisoning or ringworm of the scalp is the local health officer called for help and advice.

Certain questions continually recur: is the time of the physician in the school most profitably spent in routine medical inspections; should physicians continue to cooperate in school medical inspection plans that fall far short of meeting minimal medical standards; is the Astoria plan of school medical advising in every way superior to the older plan of medical inspecting; should all physicians who serve schools have some preservice instruction in school organization and administration; what methods have been found effective for procuring the correction of physical defects found on medical examination; how can the physical education program be adapted to the varying health needs of the individual children, and how can the health teaching program and the health service program best be coordinated?

A Conference on the Cooperation of the Physician in the School Health and Physical Education Program is being held October 16 to 18 under the auspices of the American Medical Association. (See Medical News of this issue for details.) Since the National Conference for Cooperation in Health Education published its *Suggested School Health Policies* (October 1945) great strides have been made in clarifying our thinking with regard to school health services. The coming Conference should further facilitate the process as the result of the pooled efforts of physicians and public health workers, teachers, administrators and health educators.

THE BIOLOGIC SIGNIFICANCE OF HYALURONIDASE

Widespread interest in the enzyme hyaluronidase followed the report[1] in 1939 that the action of this enzyme parallels closely the action of "spreading factor." This factor has been known since 1928 as a substance which, when injected together with a suspension of bacteria or of india ink, promotes invasion into the tissues. This action is accomplished by the hydrolysis of hyaluronic acid, a viscous mucopolysaccharide which seems to bind water in the interstitial tissues and to act ordinarily as a physical barrier to invasion by foreign substances. A comprehensive review of the biologic significance of hyaluronic acid and hyaluronidase has recently been published.[2]

Hyaluronic acid has been isolated from the aqueous and vitreous humor, the umbilical cord, synovial fluid, a number of tumors and hemolytic streptococci. It probably occurs in small concentration in connective tissue but has not been isolated from this source. The precise chemical structure is unknown. On hydrolysis equimolar quantities of hexosamine, acetyl and uronic acid have been found. On injection into animals, hyaluronic acid exhibits no antigenicity. The enzyme hyaluronidase has been found to be present in many bacteria, in bee venom, in the venom of many poisonous snakes, in extracts of testes and in other biologic material. Normal human serums contain an inhibitory factor which partially inactivates it. The situation is made more complex by the reported existence of other factors which inhibit the inhibiting factors.[3] Antiserums may be prepared to various preparations of hyaluronidase, but these are strictly specific for the source of the enzyme. However, no antiserums have yet been prepared for highly purified testicular hyaluronidase. The role of testicular hyaluronidase probably is confined to the dispersion of cumulus cells in the process of fertilization. Some apparently normal semen has been found to be deficient in hyaluronidase, and the application of hyaluronidase to the cervix is said to have increased considerably the number of successful fertilizations. A relation between hyaluronidase and rheumatic diseases is suggested by the inhibiting action of small amounts of sodium salicylate on the spreading of india ink or dye injected together with hyaluronidase.

[2] Meyer, Karl: Physiol. Rev. **27:** 335, 1947.
[3] Haas, Erwin: J. Biol. Chem. **163:** 63 (April) 1946.

A number of studies have been made on the relationship between virulence of bacteria and hyaluronidase formation, but in general there seems to be no convincing correlation. Repeated injections of testicular hyaluronidase have protected mice against lethal doses of streptococci, an action attributed to the hydrolysis of the hyaluronate capsule of the infecting organism. Since the spread of infection from one part of the organism to another involves physical transfer, continued study of the factors which limit and control the rate of this movement seems promising.

CONTROL OF RABIES

The Committee on Public Health Relations of the New York Academy of Medicine presents in a recent issue of Public Health Reports[1] a comprehensive analysis of the problem of rabies control. The analysis is based on information gathered from the replies to questionnaires distributed to state health departments, the provincial health authorities of Canada, the Bureau of Animal Industry of the United States Department of Agriculture, the United States Public Health Service, the Veterinary Division of the Office of the Surgeon General of the United States Army, the United States Livestock Sanitary Association, the American Veterinary Medical Association, the National Research Council and the various research projects sponsored by the Rockefeller Foundation. Statistics collected by the Bureau of Animal Industry since 1938 show that the incidence of rabies in men and animals increased in 1943, after a downward trend from 1939 to 1942, and reached a peak in 1944. The 1944 report of the Committee on Rabies of the United States Livestock Sanitary Association emphasizes the seriousness of the situation.

An intensive investigation of rabies was carried on from November 1936 to December 1945 by the International Health Division of the Rockefeller Foundation in cooperation with the Alabama State Board of Health. During the nine year investigation, field and laboratory studies of the disease and of the existing methods of control were under the direction of Dr. Harald N. Johnson. The Alabama studies showed that a single injection of 5 cc. of a potent vaccine will produce a high degree of immunity that is satisfactory for one year. The Rabies Research Laboratory at Montgomery has now been taken over by the United States Public Health Service, which is continuing the studies inaugurated by Dr. Johnson on the efficacy of new canine rabies vaccines. Until recently the protection afforded by vaccination in rabies was uncertain. Prophylactic vaccination of animals is now a practical possibility. With the development of the Habel test for potency, based on earlier work by Webster, and with new methods of producing better vaccines a high level of effectiveness can be attained.

Webster and Dawson in 1935 developed a mouse inoculation test for diagnosis which is more sensitive than any biologic test previously used and more accurate than microscopic examination. Studies of the virus, its distribution in the tissue of victims of rabies and its characteristics under varying conditions have revealed information that has contributed materially to the production of more effective vaccines and to more accurate knowledge of manifestations of the disease. Levinson and his associates at the Michael Reese Research Foundation, Chicago, produced in 1944 a potent inactivated virus vaccine with ultraviolet radiation from a new type of lamp which is a source of both total and extreme ultraviolet. Habel suggested recently that the use of serum or serum in combination with vaccine may bring about effective prophylaxis against rabies in men. Injection of serum might be given immediately to a person bitten by an animal suspected of having rabies. Administration of vaccine might then be deferred until the mouse test for diagnosis could be completed, which can be done in six days. If the diagnosis is positive, there is still time for effective treatment; if it is negative, the person has been spared the rather arduous Pasteur treatment.

The committee recommends that efforts should be made to secure uniform national control measures against rabies; that rabies in any animal or human being should be made reportable in all state and local units of health jurisdiction, the figures to be published in Public Health Reports; that every state should require annual licensing of dogs, and in urban areas the granting of a dog license should be made contingent on vaccination. The National Research Council on Nov. 26, 1945 reported that a single injection of 5 cc. of an approved vaccine is effective for use in mass vaccination programs and that three injections of 5 cc. each, administered a week apart, provide greater immunity and should be advised when practical. The United States Public Health Service or the Bureau of Animal Industry, or both jointly, should be urged to formulate standard quarantine procedures covering the various situations that arise during an outbreak of rabies and to recommend these to the states and territories for adoption. An educational program should be launched by appropriate health authorities to explain the necessity for control measures and to emphasize the efficacy of the vaccines now approved by the Bureau of Animal Industry and the National Institute of Health.

Current Comment

MEAT IN THE DIET OF INFANTS

The incorporation of meat in the diet of infants was not common before the introduction of commercially prepared products. Meat juices were sometimes used, and beef was laboriously scraped by the mother. In the early thirties commercially prepared vegetable and meat mixtures of good quality were introduced. Recently products solely of meat have also been studied and accepted by the Council on Foods and Nutrition. Long term studies are needed, which would extend over two or three years so that the effects of meat in the infant diet could be measured objectively in terms of height, weight and other variables. Our present knowledge of the role of meat in the infant's diet is largely empirical. The work of Leverton and Clark[1] is one of the few *objective studies undertaken in this field. An extension* of the study of the role of meat in the infant's diet might well open a new chapter in infant feeding procedures.

THE LAG IN DISTRIBUTION OF MEDICAL KNOWLEDGE

One of the most serious problems in world medicine is the inevitable lag that occurs between the introduction of a well established procedure and its availability for the mass of physicians who must apply it in the care of the sick. Graduate medical education is one of the methods by which this lag is shortened. Much attention is being given now in the United States to technics for providing general practitioners with detailed information concerning new and well established technics. In a recent issue of *The Medical Journal of Australia,* Dr. Kempson Maddox presents some interesting observations concerning the lag as it affects the Australian physician: "I propose to restrict my remarks to consideration of some therapeutic practices which I observed during a six-months medical tour of North America in 1946. In many medical centres in that country some of these practices would no longer necessarily be called as 'recent,' so long is the lag which confronts Australian medical practitioners, who are in my opinion handicapped by an outmoded undergraduate training, by long distance from the great medical research institutions of the world, by a relative paucity of physicians in contact with our own academic or research institutions, by the lack of enterprise of local agents for overseas drughouses. The actual fact is that only a fraction of even the metropolitan section of our profession is 'library-minded,' and that for one-third of the last thirty years our medical couriers have been in uniform, so that it is not surprising that Australian medicine, while always sincere and usually satisfactory, has never (recently at least) really been up to date. To correct this it is obvious that we must have more and more exchange fellowships, post-graduate lecturers and guest physicians, must make more use of library facilities and visual aids, must establish more and more post-graduate facilities in the teaching hospitals, must send more lecturers to tour the country towns, must harass the representatives of the drug houses of the western world until we obtain better and more prompt supplies of modern therapeutic weapons. I advise every physician in Australia to subscribe to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION and to resolve to visit the United States at least once during the course of his professional career." The American medical profession may take pride in this commendation, and the commendation emphasizes our responsibility. The conditions to which our Australian colleague refers apply equally and perhaps even more to medical practice in most of the Latin American countries. There undergraduate medical training is outmoded and economic conditions make difficult the receipt of important medical literature from the rest of the world.

FLUID BALANCE IN WAR EDEMA

As part of a comprehensive study of the state of undernutrition such as occurs in some European areas, Henschel, Michelson, Taylor and Keys[1] have reported changes in plasma volume and extracellular fluid in 32 normal young men subsisting on a European type of famine diet for a period of twenty-four weeks. These investigators found that as the body weight decreases on the low caloric diet the plasma volume, measured by a dye method, and the extracellular fluid, measured as thiocyanate space, remain essentially constant at their prefamine levels. It is only when compared on the basis of diminishing body weight that the plasma volume and extracellular fluid appear to increase, to the extent of about 40 per cent. All values returned to normal after about five months of refeeding. Clinical edema appeared in 28 of the subjects, but this was not until the extracellular fluid surpassed 8 to 10 per cent of the body weight in excess of that present in the normal person. Thus it appears that the edema of simple caloric starvation may be considered to be simply a reflection of a reduction in cellular mass without large change in the absolute amount of extracellular fluid.

Rh BLOOD TESTS IN DISPUTED PATERNITY CASES

In a disputed paternity case that arose in New York recently the wife, husband and child submitted to the usual blood grouping tests, with the result that the blood of all three was found compatible. Despite this finding, the husband insisted that he was not the father of the child and Rh blood grouping tests were made which ruled out the husband as the father. Justice Panken of the Domestic Relations Court was convinced by the testimony of the expert witness who performed the Rh tests and, although he could not find reference to any court case involving the efficacy of the procedure, he held that the husband was not the father of the child. In reaching his decision, Justice Panken referred to a JOURNAL editorial of June 17, 1944, which stated that "medicolegal application of the Rh blood types in cases of disputed parentage is justified, provided suitable potent reagents are available."

ORGANIZATION SECTION

Official Notes

MEETING OF THE BOARD OF TRUSTEES, CHICAGO, SEPT. 4-5, 1947

The meeting of the Board of Trustees in Chicago September 4 to 5 was fully attended, with the exception of Dr. Charles W. Roberts, who died July 28. The Board unanimously elected, as a successor to Dr. Roberts, Dr. Wingate M. Johnson, Winston-Salem, N. C., to serve until the next annual session of the House of Delegates. As is customary, the election was held in executive session.

The following resolutions on the death of Dr. Charles W. Roberts were adopted:

WHEREAS, Dr. Charles Wesley Roberts has been taken from our midst since our last meeting, and

WHEREAS, Dr. Roberts had given long devoted service to organized medicine, and

WHEREAS, He had served on the Council on Industrial Health, as a member of the House of Delegates and as chairman of the Committee on Scientific Exhibits, and

WHEREAS, At the time of his death he was serving in his second term as a member of the Board of Trustees and was a member of its Executive Committee, and

WHEREAS, His death will be deeply felt by the American Medical Association; therefore be it

Resolved, By the Board of Trustees of the American Medical Association at its meeting on Sept. 4, 1947 that it wishes to record its sense of personal loss and to extend its deep sympathy to his family; and be it further

Resolved, That this resolution be spread on the minutes of the meeting of the Board published in THE JOURNAL and a copy sent to his family.

Resignation of Dr. S. J. Seeger

The Board of Trustees accepted the resignation of Dr. Stanley J. Seeger from his position as chairman of the Council on Industrial Health.

Woman's Auxiliary

The Board provided for a joint meeting of the Board of Trustees with the Board of Directors of the Woman's Auxiliary of the American Medical Association at a meeting to be held in Chicago on November 6.

Chicago Session in 1948

The Board of Trustees appointed Dr. Warren W. Furey, president of the Chicago Medical Society, as chairman of the Local Committee on Arrangements for the Chicago Session in 1948. The session will begin June 21 and continue through June 25. The exhibits will be installed on Navy Pier. Some of the sections will meet on the Pier and others in large halls closely adjacent.

International Relations

The Board gave consideration to the present status of cooperation with the World Medical Association, which meets in Paris during September 1947.

The Board also received a report from the Editor on a visit to the Pan-American countries and present relations with the Federacion Medica Pan America.

Cooperation with the Dental Profession

The Board of Trustees received a report from Dr. George F. Lull, Secretary of the Association, on a recent visit to the annual session of the American Dental Association and arrangements for further liaison with dentistry. The proposal has been made for the establishment of liaison with the dental profession at the state and county levels.

Report on Aid to the Secretary of the Interior

As has been reported in THE JOURNAL, arrangements had been made for sending a group of physicians to aid in the medical problems of Alaska. Letters of commendation have already been received from physicians in Alaska on the excellent services rendered by this group. Dr. George Lull announced that arrangements have been made with the Southwestern Medical Foundation for assembling a group of physicians in Dallas, Texas, to aid in the care of Indians in the United States. Other groups are in process of formation for visits to Puerto Rico and the Virgin Islands.

Liaison with Other National Organizations

Reports were received on liaison with the American Public Health Association, the National Association for the Employment of the Handicapped, the United States Chamber of Commerce, the National Association of Small Businesses and other groups.

Dr. F. H. Arestad was selected to advise with a committee of the American Hospital Association, which is directing the national student nurses recruitment program.

Drs. J. R. Miller, Louis H. Bauer, Thomas McGoldrick and Dean F. Smiley and Mr. George Cooley have been appointed to a Joint Committee of the American Public Welfare Association, the American Public Health Association, the American Hospital Association and the American Medical Association to devise principles for improvement in the care of the chronically ill.

Drs. Rustin MacIntosh and Louis H. Bauer have been reelected to represent the American Medical Association on the American Council on Rheumatic Fever.

Resolutions from the House of Delegates

The Board acted on resolutions referred from the House of Delegates and appointed the following committees: one for liaison with the Veterans Administration on the medical care of veterans, one on the general practice of medicine and one on rebates, as well as a council on national emergency medical service.

The Board also considered resolutions on public relations and authorized negotiations toward the securing of public relations counsel. A resolution on the celebration of centennials by the various sections was approved, and arrangements were made to notify the sections of such centennials as they occur.

Cooperation with American College of Surgeons

The Board of Trustees appointed a committee to cooperate with a special committee appointed by the American College of Surgeons to confer on problems of mutual interest in the advancement of their respective activities.

The Council on Scientific Assembly

Announcement was made of the election of Dr. Henry R. Viets as chairman of the Council on Scientific Assembly. This Council met in Chicago at the same time as the Board of Trustees and developed a suitable program for the Supplemental Session to be held in Cleveland on Jan. 5-8, 1948.

Committee on Nursing Problems

The Board discussed problems related to nursing and confirmed the appointment of Dr. T. P. Murdock as chairman of the Committee on Nursing Problems.

Affiliation of Medical Students

Arrangements were made to develop the necessary procedure for the affiliation of medical students with the American Medical Association and for the reestablishment of a section for students in The Journal of the American Medical Association.

Centennial of Dr. William Osler

A suggestion was received for a special issue of The Journal in honor of the centennial of Dr. William Osler. The Board of Trustees recommended that an issue of the *Archives of Internal Medicine* be dedicated for this purpose. The editorial board of that publication has agreed to develop such an issue.

Archives of Dermatology and Syphilology

The Board of Trustees approved special issues of the *Archives of Dermatology and Syphilology* honoring in successive years Dr. Howard Fox, Dr. G. M. MacKee and Dr. U. J. Wile.

Increase in Dues and Subscriptions

In view of increasing costs of paper and labor and in view of increasing demands on the headquarters staff for services to members of the medical profession, the Board will recommend to the House of Delegates an increase in the annual Fellowship dues and subscription to The Journal from $8 to $10 beginning with 1948.

Motor Vehicle Accidents

The increasing rise in the number of motor vehicle accidents caused the Board of Trustees to take action leading toward the publication of an annual report in The Journal on motor vehicle accidents throughout the United States, to be developed if possible in cooperation with the National Safety Council.

Dr. Loren Avery was appointed to the Association's Committee to Study Motor Vehicle Accidents by the Board of Trustees, the Chairman of which is Dr. Herman A. Heise of Milwaukee.

Medal for General Practitioner

As announced in an editorial in The Journal for September 13, the Board of Trustees has established a General Practitioner's Medal for Exceptional Service. This medal is to be awarded each year at the Supplemental Session of the American Medical Association.

Broadcasting

A contract with the National Broadcasting Company for another series of twenty-six radio programs, under the title "Doctors Today," was approved.

Affairs of the Association

The Board of Trustees considered various criticisms of the activities of the Association and took appropriate action relative to investigation and reply.

New Legislation

Attention was given to new legislation affecting the medical profession. The Board of Trustees, after a conference with the members of the Council on Medical Service, appointed a committee, including members of the Executive Committee of the Board, the headquarters staff and representatives of the Council on Medical Service, to take prompt action relative to the points of view of the American Medical Association when new legislation is introduced.

Finances

The Board received its usual report on finances and investments and gave careful consideration to proposed budgets as related to the income of the Association.

Cooperative Medical Advertising Bureau

Attention was given by the Board of Trustees to the discontinuance of California and Rhode Island as members of the Cooperative Medical Advertising Bureau. The Editor of The Journal was authorized to prepare a special editorial dealing with the problems of advertising in state medical publications.

Surgical Procedures

The Editor of The Journal was authorized to publish each year a statement from leading hospitals in the United States as to the number and character of surgical operations performed that fall into certain groups and the general results of such operative procedures.

Miscellaneous

In its usual consideration the Board discussed problems of publication and printing as related to the various periodicals of the Association, the American Medical Directory and the Quarterly Cumulative Index Medicus; it considered the status of various problems of the Association and other matters of administration of the headquarters office.

Associate Editor

The Editor of The Journal announced the employment of Dr. Richard J. Plunkett as Associate Editor, to report for duty in the headquarters office Oct. 1, 1947.

Hospital Competition with Private Practice

The Board authorized the sending of the following resolution, which was adopted by the House of Delegates, to all hospitals on the approved list of the Council on Medical Education and Hospitals, to the superintendent and chief of staff of each hospital and to county medical societies:

Resolved, That the House of Delegates of the American Medical Association is in complete agreement with the recommendations of the West Virginia State Medical Association in its opposition to the encroachment by hospitals and other organizations on the private practice of medicine; and be it further

Resolved, That all fees for medical services be set by and collected by or for doctors of medicine rendering this service, and that all policies and practices involving medical services be approved by the medical board or medical staff before being put into effect; and be it further

Resolved, That the Council on Medical Education and Hospitals recommend strongly that all hospitals conform to these resolutions; and be it further

Resolved, that the House of Delegates of the American Medical Association go on record as strongly disapproving this practice of encroachment, and that notice of this action be sent to the American, Protestant and Catholic hospital associations and to Blue Cross organizations.

Additions to Official Bodies

Dr. W. E. Grove of Milwaukee and Dr. Derrick Vail of Chicago have been added to the Council on Physical Medicine.

Dr. Frances A. Hellenbrandt of Richmond, Va., has been elected to the Committee on American Health Resorts.

Dr. W. L. Benedict and Mr. John Bradley have been reelected to the Committee on Medical Motion Pictures.

Policy Regarding Membership on Councils

The Board decided that no physician who accepts a retainer from any industrial medical organization shall be a member of any of its councils or bureaus.

SURVEY HEALTH OF INDIAN TRIBES

Five physicians from the Southwestern Medical College, Dallas, Texas, left September 13 for Window Rock, Ariz., where they will survey health conditions on the Navajo Indian reservation for Secretary of Interior Krug. The survey will require at least two weeks and may include the Hopi and Zuni reservations as well as the Navajo reservation.

The team of six Dallas physicians is the second to be sent on a health survey by the Secretary of Interior's office. Last July 19 a team of five Chicago physicians (The Journal, July 26, 1947, page 1097) was sent to Alaska to make a similar survey among Eskimos, Indians and Aleuts. In December, 10 or 12 physicians will be sent to Puerto Rico and the Virgin Islands to do what they can in the span of a few weeks to improve health conditions. The American Medical Association has been assisting the Secretary of Interior's office in selecting the teams.

The Dallas team is composed of Drs. Ozro T. Woods, chairman; Arthur Grollman, internist and nutritionist; Martin Buehler, internist; Francis Reichsman, tuberculosis specialist; Salmon Halpern, pediatrician, and John Henry Fish, ophthalmologist.

CONFERENCE ON COOPERATION OF PHYSICIAN IN SCHOOL HEALTH AND PHYSICAL EDUCATION PROGRAM

Invited representatives of the various State Departments of Health, State Departments of Education, State Medical Associations and State Education Associations will meet October 16 to 18 at the Hotel Moraine, Highland Park, to discuss means of putting into successful operation the policies regarding school health services enunciated by the National Conference for Cooperation in Health Education in October 1945. A group of nationally known specialists in school health problems will serve as discussion leaders and consultants. The Conference is being sponsored by the American Medical Association.

Council on Medical Service

GROUP HEALTH INSURANCE COVERAGES

(From a paper presented by H. L. Rietz, Metropolitan Life Insurance Company, before the Rhode Island Medical Society

In considering plans providing for the prepayment of any portion of the cost of illness, it is essential to have an understanding and appreciation of the facilities now available for such purposes. The field is not a new one. Much has been accomplished and continuing progress is being made in providing various forms of health insurance on a voluntary basis. The record of the past twenty-five years demonstrates the effectiveness and the adaptability of voluntary insurance in providing funds for the loss of earnings and expenses due to illness. The further development and amplification of such insurance plans are dependent on mutual understanding and cooperation between insurance companies and the medical profession.

Weekly cash indemnity benefits designed to compensate the employee for loss of income resulting from sickness or nonoccupational accident have been issued under Group Insurance policies since the early 1920's. With the development of basic data from their experience under such benefits and a gradually increasing demand for broader benefits, the insurance companies have been issuing Group Hospital Expense Insurance since about 1935, Group Surgical Operation Insurance since about 1938, and are now offering Group Medical Expense Insurance.

The Group Hospital Expense Insurance provides a daily benefit of fixed amount for each day of hospitalization up to a prearranged maximum, which is usually either thirty-one or seventy days. Reimbursement is usually also provided for Special Services rendered in the hospital, such as Laboratory Services, Operating Room Expense and Anesthesia—but not doctors' fees—to a total of five or ten times the daily benefit.

Group Surgical Operation Insurance is designed to reimburse for actual fees charged for designated operations subject to specified maximum amounts set forth in a schedule in the policy. These amounts are graded by type of operation, with an overall maximum of fixed amount, usually $150, although schedules with both larger or smaller maximums are issued.

Later in 1939 and 1940 respectively these two groups were extended to cover dependents of employees.

Although the older Group Accident and Health Weekly Indemnity Benefit has attained the broadest acceptance to date, and is still growing rapidly, the Hospital Expense and Surgical Operation Benefits have met with very substantial acceptance in a relatively short period since their introduction. Since the end of 1946 there have been in the United States about 5,800,000 employees and 4,750,000 dependents insured under Group Hospital Expense policies issued by the Life and Casualty companies. Similarly, about 5,400,000 employees and 2,500,000 dependents were insured by such companies under Group Surgical Operation policies.

That such coverages are growing at a substantial rate is indicated by the fact that the number of persons in the United States covered by Hospital Expense and Surgical Benefits in insurance companies increased by approximately 2,750,000 and 2,400,000 respectively in 1946.

When it is considered that these levels of coverage have been attained through voluntary means, within a period of twelve years or less, during which administrative procedures and sales technics also were developed and perfected, the adaptability of insurance companies' services in providing such benefits is apparent. Moreover, three points should be emphasized:

1. This development has been entirely through voluntary means.

2. It has been done without attempting to dictate to or interfere in any way with the medical profession or the traditional relationship between physician and patient.

3. New forms of coverage are constantly under study or experimentation by individual companies.

As an illustration of this third point, within recent months some companies have been experimenting on a more or less limited basis with Physicians' Attendance or Medical Expense Benefit Insurance. In some cases the benefit granted is a fixed amount per day for physician's attendance while the employee is hospitalized, subject to a specified maximum. In other cases benefits may be provided for both office and home calls for medical attention.

The trend toward the various forms of insurance coverage described is pronounced. With cooperation between the insurance companies and the organized medical profession, their continued development can be greatly facilitated on a basis satisfactory to the community, the physician and the insurance industry and operate to the best interests of all concerned.

For the five year period 1942 to 1946 this company (Metropolitan Life) returned on its Group Disability coverages 82 cents of every premium dollar in claims and dividends. Of the remaining 18 cents slightly less than 11 cents were used for expenses and the remainder, of about 7 cents, was required for taxes and contingency reserves.

While the figures cited relate to the experience under group coverages written by Life and Casualty companies, other forms of benefit plans have been developed and have enjoyed a substantial growth during recent years. For persons who are self-employed or employed in groups too small to qualify for regular forms of Group Insurance, there are available a wide variety of individual Accident and Health policies. In addition, hundreds of thousands of persons are eligible for benefits in event of sickness through membership in mutual benefit associations, fraternal societies and trade union plans. In addition to this, there is the Blue Cross Plan, which after approximately fifteen years of operation provides hospital benefits on a service basis to over 26,000,000 people in this country.

Insurance companies have developed the technics for the sound marketing, underwriting and administration of the forms of insurance described. They are aggressively developing such business on a voluntary basis, but they have no desire whatever to dictate to the medical profession or interfere with their rights and privileges.

However, it is apparent that the medical profession can make a positive contribution to the continuation and further development of voluntary insurance plans free from any suggestion of outside compulsion. To this end, it is highly desirable that:

1. The medical profession should adopt a schedule setting forth the relative values of the various surgical procedures.

2. Based on such relative values, the medical profession should adopt a schedule of dollar fees for the various surgical procedures which the majority of its members would accept in full payment for persons whose incomes are below a specified maximum.

3. The medical profession should urge its members to participate in such plans and to accept the schedule fees in full payment within the income limit.

Washington Letter

(From a Special Correspondent)

Sept. 18, 1947.

Veterans of Foreign Wars Charge Abuses in Veterans Medical Service

Veterans Administrator Omar Bradley has been asked by a resolution of the Veterans of Foreign Wars to consider recommendations for "the correction of abuses presently existing within the (Veterans) Medical Service." A resolution which was cleared through the VFW Rehabilitation Committee charged: (1) that the Veterans Administration Medical Service has undertaken to train physicians at cost of "vast sums of money" and that few physicians so trained will remain with the agency; (2) that some phases of training "appear to be foreign to accepted and legal principles of medical treatment"; (3) that requested inquiries into training and hospital conditions "have been smothered, ignored or conducted by inexperienced or incompetent investigators"; (4) that "vast sums have been spent in 'public relations' to publicize the medical service," and (5) that there is "woeful lack of cooperation between the medical service and other operational services within the Veterans Administration."

Atomic Energy Commission to Safeguard Health and Safety Conditions in Plants

The United States Atomic Energy Commission has appointed an advisory board, headed by Sidney J. Williams of Evanston, Ill., assistant to the president of the National Safety Council, to study public health, industrial and fire protection conditions in various atomic installations. The ten man board will tour the plants by chartered plan. They include radiologic specialists and health and safety authorities. Starting at the Oak Ridge, Tenn., plant the group is to visit atomic plants at Chicago; Berkeley, Calif.; Hanford, N. Y., and Boston. Among the board members are Dr. Philip Drinker, Harvard School of Public Health; Richard Fondiller, New York actuarial consultant; Dr. Hymer Friedell, Western Reserve University radiology professor; Dr. Herbert M. Parker, Richland, Wash., radiation protection adviser, and Dr. Abel Wolman, Johns Hopkins University sanitary engineering expert.

Navy Dental Corps Separated from Medical Department

Navy Department announced that its Dental Corps has been removed from supervision of the Medical Corps and will operate as a separate entity on all ships and stations. New regulations implementing the change set up a new Dental Department aboard ships and at shore installations and provide that a Dental Corps officer shall be the head of the Dental Departments of each. Dental Corps officers will command naval dental schools, dental technician schools, base and post dental detachments and separate dental clinics.

Bureau of Standards Reports Diamonds are Best Gage of Radioactivity

The National Bureau of Standards announced after extensive laboratory tests that diamonds are a better measure of radioactivity than man-made counting equipment. Single-crystal colorless diamonds can be used to count gamma rays given off by radioactive materials in the same way as the Geiger-Muller counter. Diamonds are a thousand or more times more sensitive to radiation, size to size, than the ordinary counter. They are virtually indestructible, while the measuring equipment lasts only a few months. Gamma radiation is used by physicians to arrest malignant growths and is also employed in industry and nuclear research.

U. S. Taking Heavy Loss on Sale of Radioisotopes to Other Nations

Dr. Paul C. Aebersold of Oak Ridge, Tenn., disclosed that the country is taking a heavy loss on the sale of radioisotopes to other nations. The United States Atomic Energy Commission is offering the radioactive materials at prices ranging from $1.10 to $52 per unit, while some of the material is estimated to have cost at least a million dollars per unit when produced by cyclotron. The commission announced that the first shipment of radioisotopes to go abroad was a small quantity of radioactive phosphorus (P^{32}) sent to Australia for treatment of a rare blood disorder. The shipment inaugurated the American policy of sharing peacetime atomic benefits with other nations.

St. Elizabeth's Hospital to Open Outpatient Department

Dr. Winfred Overholser, superintendent, St. Elizabeth's Hospital, announced that beginning this fall an outpatient clinic will be opened to serve patients with minor or emotional ills. Dr. Overholser regards the plan as "one of the most important in the hospital's history."

Coming Medical Meetings

Conference of State Medical Society Secretaries and Editors, Chicago, A.M.A. Headquarters, Nov. 7-8. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

American Academy of Neurological Surgery, Colorado Springs, Broadmoor Hotel, Oct. 9-11. Dr. T. C. Erickson, 1300 University Ave., Madison 5, Wis., Secretary.

American Academy of Ophthalmology and Otolaryngology, Chicago, Palmer House, Oct. 12-17. Dr. W. L. Benedict, 102 Second Ave. S.W., Rochester, Minn., Secretary.

American Anti-Arthritis Association, Del Mar, Calif., Oct. 4-5. Dr. Robert T. Pottenger, 65 N. Madison Ave., Pasadena, Calif., Secretary.

American Clinical and Climatological Association, Colorado Springs, Oct. 13-15. Dr. James Bordley III, Johns Hopkins Hospital, Baltimore 5, Secretary.

American Hospital Association, St. Louis, Sept. 22-25. Mr. George P Bugbee, 18 E. Division St., Chicago, Exec. Secretary.

American Public Health Association, Atlantic City, Oct. 6-10. Dr. Reginald M. Atwater, 1790 Broadway, New York 19, Executive Secretary.

American Society for the Study of Arteriosclerosis, Chicago, Hotel Knickerbocker, Nov. 2-3. Dr. O. J. Pollak, Wilmington General Hospital, Wilmington 14, Delaware, Secretary.

American Society of Clinical Pathologists, Chicago, Drake Hotel, Oct. 28-30. Dr. A. S. Giordano, 531 N. Main St., South Bend, Ind., Secretary.

Association of American Medical Colleges, Sun Valley, Idaho, Oct. 27-29. Dr. Fred C. Zapffe, 5 S. Wabash Ave., Chicago, Secretary.

Association of Medical Illustrators, New Orleans, Sept. 29-Oct. 2. Miss Muriel McLatchie, Massachusetts General Hospital, Boston, Secretary.

Association of Military Surgeons of the United States, Boston, Nov. 13-15. Col. James M. Phalen, Army Medical Museum, Washington 25, D. C., Secretary.

Central Neuropsychiatric Association, Galveston, Texas, Oct. 17-18. Dr. William C. Menninger, 3617 W. Sixth Ave., Topeka, Kans., Secretary

Delaware, Medical Society of, Wilmington, Oct. 13-15. Dr. John F. Hynes, Memorial Hospital, Wilmington, Secretary.

District of Columbia, Medical Society of the, Washington, Hotel Statler, Oct. 6-8. Mr. Theodore Wiprud, 1718 M Street N.W., Washington 6, Secretary.

Indiana State Medical Association, French Lick, Oct. 28-30. Mr. Ray E. Smith, 23 E. Ohio St., Indianapolis 4, Executive Secretary.

International College of Surgeons, U. S. Chapter, Chicago, Palmer House, Sept. 29-Oct. 2. Dr. Louis J. Gariepy, 16401 Grand River Ave., Detroit 27, Secretary.

Inter-State Postgraduate Medical Association of North America, St. Louis, Public Auditorium, Oct. 14-17. Dr. Tom B. Throckmorton, 406 Sixth Ave., Des Moines, Iowa, Secretary.

Kansas City Southwest Clinical Society, Kansas City, Mo., Municipal Auditorium, Oct. 6-9. Mr. E. Leas Clower, 630 Shukert Bldg., Kansas City 6, Executive Secretary.

Kentucky State Medical Association, Louisville, Sept. 29-Oct 2 Dr P. E. Blackerby, 620 S. Third St., Louisville 2, Secretary.

Michigan State Medical Society, Grand Rapids, Pantlind Hotel, Sept. 23-26. Dr. L. Fernald Foster, 2020 Olds Tower, Lansing 8, Secretary.

Mississippi Valley Medical Society, Burlington, Iowa, Oct. 1-3. Dr. Harold Swanberg, 510 Maine St., Quincy, Ill., Secretary.

New England Postgraduate Assembly, Boston, Copley-Plaza Hotel, Oct. 29-31. Dr. Leroy E. Parkins, 8 Fenway, Boston 15, Chairman.

New York State Association of Public Health Laboratories, Albany, Nov. 7. Miss M. B. Kirkbride, New Scotland Ave., Albany 1, Secretary.

Oklahoma City Clinical Society, Oklahoma City, Biltmore Hotel, Oct. 27-30. Dr. Elmer R. Musick, 512 Medical Arts Bldg., Oklahoma City, Director of Clinics.

Omaha Mid-West Clinical Society, Omaha, Oct. 27-31. Dr. John M. Thomas, 1031 Medical Arts Bldg., Omaha 2, Secretary and Director of Clinics.

Southern Psychiatric Association, Birmingham, Ala., Oct. 13-14. Dr. Newdigate M. Owensby, 384 Peachtree St. N.E., Atlanta, Ga., Secretary.

Southwestern Medical Association, Phoenix, Ariz., Hotel Westward Ho, Nov. 6-8. Dr. Louis W. Breck, 116 Mills St., El Paso, Texas, Secretary.

Vermont State Medical Society, Burlington, Hotel Vermont, Oct. 1-3. Dr. Theodore H. Harwood, 128 Merchants Row, Rutland, Secretary.

Virginia, Medical Society of, Roanoke, Oct. 13-15. Miss Agnes V. Edwards, 1200 E. Clay St., Richmond 19, Secretary.

Washington State Medical Association, Seattle, Olympic Hotel, Sept. 28-Oct. 1. Dr. Harold E. Nichols, 327 Cobb Building, Seattle, Secretary.

Wisconsin, State Medical Society of, Milwaukee, Hotel Schroeder, Oct. 6-8. Mr. Charles H. Crownhart, 110 E. Main St., Madison 3, Secretary.

Volume 135
Number 3

GOVERNMENT SERVICES

ARMY

TO THE MEDICAL PROFESSION AND TO FORMER MEDICAL OFFICERS OF THE ARMY

R. W. Bliss, Major General, the Surgeon General

I am using this means of communication to acquaint you with the changes which have been made in the Medical Department of the United States Army since the war and to invite you to continue your interest in the department.

The Armed Services must be supplied in peacetime as well as in wartime with superior medical service. To accomplish this we must have a reasonable number of medical officers in our Regular Army Medical Corps. Our immediate goal is three thousand regular medical officers to furnish care for approximately one and one-half million persons. We are presently far short of this goal. The doctors who must be obtained to make up our present deficit must be imbued with the highest professional standards. Poor personnel will solve no difficulties and will actually make any long term solution hopeless. We cannot secure these qualified doctors for the Army without your utmost cooperation. To have your cooperation our professional standards and their application must command your complete respect.

We in Army medicine are proud of our Corps. We are proud of the contributions we have made to American medicine in the past, and we intend to act in such manner as shall make us proud of its future accomplishments. The opportunities for the practice of superior medicine are great in the Army. These opportunities will be increasingly greater as the coordination of all medical activities of all the government medical services takes clearer form. This progressive coordination is inevitable. By the closest cooperation with many of the leaders in civilian American medicine, we have attempted and, I believe, are accomplishing the rehabilitation of Army medicine on a broad and solid base.

I outline some of the things which have taken place in the Army medical service since the end of the war:

We have an extensive training program in operation. Ninety-nine members of the Medical Corps are now diplomates of the various American Specialty Boards. Twenty-five others have completed the first half of their board requirements and an additional nine have been accepted for examination. We have established approved residency training in many of our Army hospitals. One hundred and ninety-eight officers are currently in this residency training. Five hundred and sixty officers have had or are having courses of varying lengths (many leading to advanced degrees) in civilian medical schools and hospitals. This September, forty-three of our able and younger medical officers will become residents or fellows in that number of outstanding medical schools. These appointments are for a two year period. During this time they will also conduct the Reserve Officers Training Corps (ROTC) medical program at these colleges. This training pace will be maintained. Nine of our general hospitals in this country have been approved as training institutions by the American Medical Association and seven hundred and thirteen leaders in civilian medicine are an integral part of the staff in consultant and teaching capacities.

In addition to the superior clinical work being done we are now spending over $4,000,000 a year on medical and surgical research. Over half of these projects are being carried out in civilian institutions. Many of these plans can be set up in Army institutions when capable doctors interested in research are available.

At the onset of World War II there was in the Medical Department one Administrative Corps officer for each seventeen doctors. A permananent Medical Service Corps has now been established, and there is now authorized a nonprofessional officer for each three officers of the Medical Corps.

Under the new Promotion Act which recently passed Congress, four years of constructive service credit is given to medical officers on entrance in the Service and this seniority is retained throughout the years. The rank of colonel is now attainable eight years earlier than was previously possible.

Effective Sept. 1, 1947 all Regular Army medical officers will be paid an additional $100 per month over all other pay and allowances.

Under this same act we now have authority to commission older and more experienced doctors in all grades up to and including that of colonel.

We have inaugurated a system of career planning. After the first few years of intern and residency training, an officer may select definite medicomilitary specialties. These are preventive medicine, clinical medicine and, as a very broad term, administrative careers, and the officer will remain in these specialties throughout his entire service.

I know you are interested in the Regular Army Medical Corps. The Army needs your continued interest in the procurement of able, ambitious young doctors for the Regular Army. In spite of our shortage, we cannot and will not lower our standards. I hope that you will advise some of your best interns and residents to consider seriously an Army career. We are prepared to train two hundred interns during the year beginning July 1, 1948. I hope that these two hundred interns will be outstanding men from your schools. I am confident that many of the ablest of these will request integration into the Regular Army at the end of their internships.

PUBLIC HEALTH IN JAPAN

The War Department has announced that Japanese health officials established a National Institute of Health May 21 to promote the health of the nation by controlling the production and assay of biologic products and to conduct research on diseases and other health problems.

Production of medical and dental supplies in Japan increased in April by 25 per cent, but the penicillin output went down 20 per cent when a fire destroyed the Kakeda Penicillin Factory.

The Japanese government took over the responsibility for the distribution of imported medical supplies and equipment from the Occupation Forces May 15.

From two to six lunches a week were being served to 5,486,619 Japanese school children on April 1. The food was supplied from former Japanese army and navy supplies, from relief food purchased from the United States imports and local resources and from donations throughout the licensed agencies for relief in Asia. The necessity for providing school lunches became evident in a survey which showed that the average height of primary school children had dropped 5 cm. from 1937 and 1946 and that the loss of weight in the same period was 3 Kg.

PERSONAL

Col. William D. Graham, M. C., has been assigned as chief of the hospital division in the Surgeon General's Office to succeed Col. Harry A. Bishop, M. C., who has been assigned to the office of the Secretary of War. Colonel Graham graduated from the University of Minnesota Medical School and entered the military service in 1934. He was awarded the Legion of Merit in the recent war for "exceptionally meritorious service" as commanding officer of the 158th General Hospital in England.

NAVY

LOCAL BOARDS FOR THE CONTROL OF RADIOISOTOPES

The Surgeon General of the Navy has directed the commanding officer of naval hospitals to form a local board for the control of radioisotopes which will be used clinically in all their institutions. This order follows a ruling by the Atomic Energy Commission that the human application of radioisotopes must be controlled by a local board in each hospital. The board will be composed of three specialists: (1) a medical officer well versed in the physiology and pathology of blood forming organs, (2) one whose specialty is metabolism and metabolic disorders and (3) a biophysicist, radiologist or radiation physiologist qualified in the technic of radioisotopes. Research in the Navy on the use of radioisotopes for the treatment of the sick is being directed by the newly formed Division of Atomic Defense of the Bureau of Medicine and Surgery.

SURGEON GENERAL INSPECTS NAVAL HOSPITALS

Surg. Gen. Clifford A. Swanson completed his tour of inspec[illegible] of naval hospitals, covering a period of several months, September 3 when he visited the naval hospital at Phila[illegible]. Again the plane trip from Washington was unique in [illegible] both the pilot and copilot were medical officers, Comdr. N. L. Barr and Capt. B. Groesbeck Jr., respectively. The surgeon general left by plane for Europe on September 8 to accompany a Congressional Committee. After the completion of his tour with the committee, he is expected to return to the United States about October 15.

NAVY AWARDS AND COMMENDATIONS

Captain Lloyd R. Newhouser

The President of the United States has awarded the Legion of Merit to Capt. Lloyd R. Newhouser (MC), U.S.N. The citation read in part as follows: For exceptionally meritorious conduct in the performance of outstanding services as head of the department of physiologic chemistry at the Naval Medical School, Bethesda, Md., from Dec. 7, 1941 to Sept. 2, 1945. Working in close collaboration with the American Red Cross, Captain Newhouser rendered services of inestimable value to the Navy by developing a program for obtaining blood and other supplies for liquid and dry plasma. In addition, he worked out a method for processing liquid plasma, designed the package for dry plasma and established the Naval Medical School as the plasma distribution center for naval hospitals within the continental limits of the United States. He further planned and put into operation the entire blood program in the Pacific war area. While acting as plasma fractionation officer, he developed the program for securing plasma fractions of a special type and designed the standard Army-Navy package for serum albumin, which proved its value under combat conditions. Again, as acting penicillin control officer for the Navy he carried out studies which led to the designing of the standard penicillin package now in general use. In all of these undertakings Captain Newhouser worked without the advantage of precedent. By his professional integrity and vision he contributed to the success of the Navy's medical program and upheld the highest traditions of the Naval Service. Dr. Newhouser graduated from Indiana University School of Medicine in 1924 and entered the naval service the same year; at present he is head of the graduate training program for the Bureau of Medicine and Surgery.

PUBLIC HEALTH SERVICE

GOVERNMENT AID FOR DEVELOPING CANCER COURSES

The National Cancer Institute is prepared to aid medical schools for further development of courses in cancer for medical students, the Surgeon General, U. S. Public Health Service, has announced. The institute received authority from Congress this year to make grants-in-aid to medical schools for this purpose. All the grants made by the National Cancer Institute in the past have been for the support of research on cancer. This new activity is being inaugurated on recommendation of the National Advisory Cancer Council, which in turn based its recommendations on the results of a conference held at the National Cancer Institute by a committee of medical educators.

The new program of aid to medical schools is designed to place greater emphasis on the integration of cancer instruction in the total undergraduate curriculum. The deans of all medical schools have been advised that the National Advisory Cancer Council is prepared to receive applications for financial assistance in expanding their cancer teaching programs.

Grants will range from $10,000 to $25,000 per year depending on the activities to be undertaken. Funds are available until spent. To assure continuity, the Surgeon General announced that funds have been set aside already for next year. It is anticipated that other agencies interested in promoting cancer control work will also give financial assistance to this program.

The committee of medical educators, whose report resulted in the new program, includes the following:

Frank E. Adair, Associate Professor of Clinical Surgery, Cornell University Medical College.
H. Glenn Bell, University of California Medical School.
Warren H. Cole, University of Illinois College of Medicine.
Harold S. Diehl, University of Minnesota.
Daniel C. Elkin, Emory University.
Roland W. Harrison, University of Chicago.
Joseph C. Hinsey, Cornell University.
Emile Holman, Stanford University.
George H. Humphries 2d, Columbia University.
A. C. Ivy, University of Illinois.
Maxwell E. Lapham, Tulane University.
Currier McEwen, New York University.
J. Roscoe Miller, Northwestern University.
John H. Mulholland, New York University.
Edward W. A. Ochsner, Tulane University.
Willard C. Rappleye, Columbia University.
Erwin R. Schmidt, University of Wisconsin.
George M. Smith, Yale University.
Francis S. Smyth, University of California.
William D. Stovall, University of Wisconsin.
Grantley W. Taylor, Harvard University.
Owen H. Wangensteen, University of Minnesota.
Milton C. Winternitz, Yale University.
Lewis H. Weed, National Research Council.

MISCELLANEOUS

SALE OF SURPLUS GOVERNMENT PROPERTY

The War Assets Administration, Denver Regional Office, 728 15th Street, is conducting a sale of surplus drugs, chemicals, hospital and surgical supplies and dental laboratory and hospital equipment including folding beds, food carts, bed frames, cabinets, operating room lamps, trays, tables, oxygen tents, bandages, stethoscopes and many other items. Persons who are veterans have certain priorities but must possess a Veteran's Certificate (WAA form 1127 or 63) showing the right to purchase the kind of property offered for sale. For detailed information concerning the Veteran's Certificate contact the Veterans Division, Room 707, Kittredge Building, Denver, or the War Assets Administration Office that is located at Mountain Road and Broadway, Albuquerque, N. M. Orders to receive proper consideration must be received in the Bid Opening Unit, 6th Floor, Commonwealth Building, 728 15th Street, Denver, by 3 p. m. September 29.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

CALIFORNIA

Tumor Record Registry.—The Chronic Disease Service of the California Department of Health has inaugurated a tumor record registry on a voluntary pilot basis in selected California hospitals. The program will be carried out in consultation with the Cancer Commission of the California Medical Association. Purposes of the registry are (1) to determine the extent of cancer morbidity in the state, (2) to permit statistical epidemiologic studies, (3) to supply leads for clinical and laboratory research, (4) to facilitate follow-up of patients, (5) to evaluate therapy and the cancer control program and (6) to furnish information for professional and lay education.

Personal.—Dr. Roy O. Gilbert, Los Angeles, has been appointed health officer of Los Angeles County. He was formerly assistant health officer and director, Bureau of Preventive Diseases, Los Angeles County Health Department.——Dr. Samuel J. McClendon, San Diego, member of the State Board of Public Health and past president of the California Medical Association, was elected president of the California Heart Association at its meeting in Los Angeles.——Dr. Herbert Bauer has resigned as county physician at San Luis Obispo and has accepted a fellowship of one year of study in public health granted by the National Institute of Health, Washington, D. C. Dr. Bauer will study at the school of public health, University of California, Berkeley.

COLORADO

Denver's First Physician Coroner.—Dr. Angelo Lapi, now a research fellow in the Department of Legal Medicine at Harvard Medical School, Boston, has been appointed coroner of the city and county of Denver, the first time in the history of the city that a doctor of medicine will hold that position. Dr. Lapi, a graduate of University of Buffalo School of Medicine, 1937, will soon publish his studies on the subject of nutritional deficiencies.

State Laboratory Expands Services.—The central laboratory of the Colorado Department of Public Health in order to fill numerous requests will enlarge its services to physicians of the state. New services to be added include total protein in spinal fluids, new rapid culture for tubercle bacilli, typing of organisms of the enteric group, mycology and laboratory evaluation. All licensed physicians in the state may avail themselves of these services.

Appoint Director of General Hospital.—Dr. James P. Dixon, Philadelphia, has been appointed director of Denver General Hospital, Denver, and will assume his duties on October 1. He has been administrative intern under Dr. Lucius R. Wilson at the Episcopal Hospital in Philadelphia and is a former fellow in public administration and hospital administration at the W. K. Kellogg and Rockefeller foundations. He graduated from Harvard Medical School, Boston, in 1943.

Department Heads Appointed.—Dr. Joseph H. Holmes, New York, has been appointed associate professor of medicine and director of postgraduate training in the basic sciences at the University of Colorado School of Medicine, Denver. A graduate of Western Reserve University, Cleveland, Dr. Holmes also did postgraduate work at Columbia College of Physicians and Surgeons, New York, where he taught physiology prior to his appointment. Dr. John M. Foster Jr., Denver, has been promoted to professor of surgery and head of the department of surgery following the resignation of Dr. George B. Packard. Dr. Foster is also attending surgeon at Children's, Mercy, Presbyterian, St. Joseph's, St. Luke's and Colorado General hospitals. Dr. Packard, head of the department for the past eight years, will continue to teach as a professor of surgery while continuing private practice. Dr. Edward S. Taylor, New York, has been named professor and head of the department of obstetrics and gynecology following the retirement of Dr. Clarence B. Ingraham, made professor emeritus after thirty years as head of the department. Dr. Taylor, a graduate of State University of Iowa College of Medicine, Iowa City, 1936, was formerly a teaching resident in obstetrics and gynecology at the Long Island College of Medicine and Long Island College Hospital in Brooklyn.

CONNECTICUT

Semiannual County Meetings.—Dates for the semiannual meetings of the eight component county associations of the Connecticut State Medical Society have been announced as follows: Fairfield County, October 1; Hartford County, October 28; Litchfield County, October 7; Middlesex County, October 9; New Haven County, October 23; New London County, October 2; Tolland County, October 21, and Windham County, October 16.

GEORGIA

Reunion of Cancer Patients.—Fifty-one patients who have survived from five to ten years following treatment of cancers held a reunion at La Grange, August 29. The patients, who ranged in age from 16 to 81 years, had been treated at the cancer clinic of the City-County Hospital.

ILLINOIS

Two More Cancer Diagnostic Clinics.—Cancer diagnostic clinics have been established in Bloomington and in Elgin. The McLean County Cancer Clinic in Bloomington was opened June 20 under the direction of Dr. Howard P. Sloan. Clinic sessions are held the first and third Fridays of each month from 11 to 12 a. m. Dr. Joel L. Deuterman is director of the Elgin center opened July 11, whose clinic sessions are scheduled for every Friday morning at 8 o'clock. This brings to twelve the number of cancer diagnostic clinics now in operation throughout the state. The clinics provide consultant services to the physician in both the diagnosis and the treatment of cancer, thus bringing the advice of specialists within the reach of as many patients as the clinics can accommodate.

Chicago

Establish Postgraduate Division.—Establishment of a postgraduate division at the University of Illinois College of Medicine for administration of widely differing kinds of advanced teaching was announced September 5, under the directorship of Dean John B. Youmans. The new division is designed to improve the character and quality of postgraduate teaching and to facilitate its extension to physicians residing outside the Chicago area. It will correlate all postgraduate courses in medicine offered at the Chicago professional colleges. Although the university has offered advanced medical courses for many years and recently has expanded its postgraduate program for veteran physicians returning from service, instruction has been conducted by individual units and departments. At least eleven courses including instruction in ear-nose-throat, diseases of the eye, basic neuropsychiatry, basic medical sciences, dermatology, pediatrics and allergy will be offered in 1947-1948. Most of the classes will be conducted for nine months' duration, although several short courses ranging from two to twelve weeks will be offered.

Postgraduate Course for Veteran Training.—The Chicago Medical Society's postgraduate course in cardiovascular diseases October 20-25 in Thorne Hall has been approved for veterans' training. It is designed both for the physician especially interested in cardiovascular diseases and for the general practitioner. The out of state faculty includes:

Francis D. Murphy, Milwaukee, Arterial Hypertension: Diagnosis and Treatment of Its Complications.
Norman M. Keith, Rochester, Minn., Diagnosis and Course of Different Types of Hypertension.
Reginald H. Smithwick, Boston, Peripheral Arterial Disease.
Max M. Peet, Ann Arbor, Mich., Newest Work on Peripherovascular Disease and Suitable Treatment.
Karl P. Link, Ph.D., Madison, Wis., The Anticoagulant Dicumarol.
Ferdinand R. Schemm, Great Falls, Mont., Observations on Relative Importance of Sodium Water and Acids in the Treatment of Edema.
William D. Stroud, Philadelphia, Rheumatic Heart Disease.
Ovid O. Meyer, Madison, Wis., Treatment of Subacute Bacterial Endocarditis.
George C. Griffith, Los Angeles, Management of the Rheumatic State.
Robert L. Levy, New York, Management of the Patient with Anginal Pain.
Harold C. Lueth, Omaha, Management of Nephritis with Edema.
Cyrus C. Sturgis, Ann Arbor, Mich., The Heart in Thyroid Disease.
Julius Jensen, St. Louis, The Heart in Pregnancy.
Roscoe L. Sensenich, South Bend, Ind.
Cecil J. Watson, Minneapolis, Some Interphase Problems in Cardiac and Liver Disease.
Ralph A. Kinsella, St. Louis, Cardiac Lesions in Lupus.

The course, which is limited to 100 physicians, has a registration fee of $50. Veterans desiring to avail themselves of the benefits to which they are entitled must file a "Certificate of Eligibility and Entitlement" with the Veterans Administration, 366 West Adams Street, Chicago. The signed form should be presented to the Chicago Medical Society at registration. Veterans residing outside Illinois may secure the certificate at the nearest Veterans Administration office and mail it to the one in Chicago. A photostatic copy of the veteran's discharge certificate must accompany the application, and if he has ever applied for benefits he should note his assigned C number.

Public Conference on Nutrition.—A conference on nutrition will be held October 1 in the John B. Murphy Memorial Auditorium, beginning at 9:30 a. m.; it is sponsored by the Chicago Medical Society in cooperation with the Chicago Nutrition Association, the Institute of Medicine, the Illinois State Medical Society and Friends of the Land. Dr. Andrew C. Ivy, University of Illinois College of Medicine, will speak on "Appetite and Hunger"; George A. Sloan, LL.D., president of the Nutrition Foundation, New York, on "The Food Industry and the Public," and Dr. Frank G. Boudreau, National Research Council, New York, on "The World Food Situation: Yesterday and Tomorrow." Dr. Jonathan Forman, editor, *Ohio State Medical Journal*, Columbus, will open the afternoon session speaking on "The Soil and Nutrition." He will be followed by Dr. Clive McCay, Cornell University, Ithaca, N. Y., "Food for the Aged"; Harold H. Mitchell, University of Illinois, Ph.D., Urbana, "Diet and Climate," and Dr. Harold P. Rusch, University of Wisconsin Medical School, Madison, "Diet and Cancer of the Liver." At the evening session, which begins at 7:30, Dr. Vilhjalmur Stefansson, New York, an Arctic explorer, will speak on "An Anthropologic Approach to Nutritional Problems" and Dr. John P. O'Neil, Chicago, on "The Citizen's Responsibility."

KENTUCKY

Expand Cancer Clinic.—The construction of an addition to the cancer clinic at St. Joseph Infirmary, Louisville, is being financed by the Sisters of Charity of Nazareth. The Kentucky division of the American Cancer Society will furnish the necessary equipment for the operation of the clinic. It will have three x-ray therapy machines and be able to handle 1,200 patients a year.

MASSACHUSETTS

Conference on Myasthenia Gravis.—A conference on myasthenia gravis will be held at the Massachusetts General Hospital, Boston, October 2-4. Drs. George H. Atcheson and Otto Krayer, both of Boston, Edith Nachmansohn, New York, and others will lead the opening discussion on neuromuscular transmission Thursday afternoon at 2 p. m. On Friday the morning meeting will be given to diagnosis and treatment and the afternoon to the problem of the thymus, thymectomy and thyroid. A clinical meeting and a discussion of future research is planned for Saturday morning. An informal dinner Thursday evening will include guests. All investigators working on the problem of neuromuscular transmission and clinicians, surgeons and patients with myasthenia gravis are welcome.

MICHIGAN

The Biddle Lecture at the Annual Meeting.—The Honorable John N. Brown, assistant secretary of the Navy for air, Washington, D. C., will deliver the Biddle oration at the annual session of the Michigan State Medical Society September 24 in the Pantlind Hotel, Grand Rapids, on "Human Engineering." It is the only lecture of the session open to the public.

NEVADA

Mental Hygiene Society Reorganized.—The reorganization of the Nevada Mental Hygiene Society has been completed following the formulated plans for incorporation. Meetings will be held on the ninth of each month in the Chamber of Commerce Hall, Reno. A committee has been set up to look into the feasibility of providing a commission on the subject of divorce which if accepted will be presented to the International Meeting on Mental Hygiene in London, 1948. The society has fifty members at present and Dr. John R. Hills, Reno, is president.

NEW YORK

Eighth District Clinical Sesson.—The annual meeting and clinical teaching day of the Eighth District branch of the Medical Society of the State of New York at Jamestown, October 1, will feature a symposium on cancer. Specialists from Roswell Park Memorial Institute, Buffalo, will discuss "Results of Experimental and Clinical Investigations of the Newer Agents in the Treatment of Cancer," "Advances in the Use of X-Ray and Radium" and "Newer Surgical Methods in the Treatment of Cancer." Papers at the morning session will be on "Problems in X-Ray Diagnosis" and "Role of the Laboratory in Diagnosis and Treatment." The Woman's Auxiliary to the Chautauqua County Medical Society will entertain the wives of physicians attending the meeting.

New York City

The Christ Church Forum.—On the program of the Christ Church forum, October 1-2, Dr. Edward H. Ochsner, Chicago, will speak Wednesday afternoon on "What's Wrong with Socialized Medicine." Thursday afternoon Dr. Charles G. Heyd, New York, will address the session on "Medical Discovery and World Peace."

The Gregory Lecture.—Dr. Alan Gregg, director, Division of Medical Sciences, the Rockefeller Foundation, will deliver the 1947 Menas S. Gregory Lecture on "The Prospects and Promises of Psychiatry" at New York University College of Medicine. It will be held October 17 at 4 o'clock in the amphitheater, psychiatric division, Bellevue Hospital.

Industrial Health Publication.—The faculty of the New York University College of Medicine is publishing a monthly magazine, *Health on the Job*, circulated among executives of about twenty thousand New York business firms. It is dedicated to new developments in the industrial health field with particular emphasis on timely interviews with medical directors of large and small firms. Medical directors of some of the nation's largest corporations are its contributors. Dr. David H. Goldstein, medical director, New York Times, and assistant professor of preventive medicine, is supervising editor.

Conference on Antihistamine Agents in Allergy.—The New York Academy of Sciences will hold a conference on Antihistamine Agents in Allergy October 3-4. Among the speakers will be:

Dr. M. Rocha e Silva, Instituto Biologica, São Paulo, Brazil, Role of Blood Platelets and Leukocytes in Anaphylaxis.
Dr. E. T. Waters, University of Toronto, Toronto, Canada, The Detoxification of Histamine.
Dr. Daniel Bovet, University of Rome, Italy, Introduction to Antihistamine Agents and Antergan Derivatives.
Dr. Rolf Meier, University of Basle, Switzerland, Antistine and Related Imidazolines.

Persons desiring to attend the conference may do so by making a request in writing to Eunice T. Miner, Executive Secretary, New York Academy of Sciences, Central Park West at Seventy-Ninth Street, New York 24.

OHIO

Poliomyelitis in Akron.—A sharp outbreak of poliomyelitis has been reported in Akron, with an unofficial estimate of 205 cases as of September 7, a figure no doubt including cases with onsets during the latter part of August. The U. S. Public Health Service is cooperating with the state and local health authorities in combating the epidemic.

Conference of the Institutum Divi Thomae.—The annual conference of the Institutum Divi Thomae and its affiliated units was held in Cincinnati September 2-5 under the chairmanship of Elton S. Cook, Ph.D., Cincinnati, dean of research. Among the subjects discussed were cancer, clinical reports, enzymes, cellular extracts and research in physics. Physicians who appeared on the program included Drs. Joseph C. Amersbach, New York; Leo G. Nutini, Cincinnati, and Morris Fishbein, Chicago, Editor, THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

Symposium on Nutritional Anemia.—A symposium on nutritional anemia, sponsored by the Robert Gould Research Foundation, Erlanger, Ky., will be held in Cincinnati October 16-18 under auspices of the University of Cincinnati College of Medicine with Elmer V. McCollum, Ph.D., Baltimore, as chairman. The program includes:

Dr. Maxwell M. Wintrobe, Salt Lake City, The Physiological Implication of the Anemic State.
Max O. Schultze, Minneapolis, The Metabolism of Iron and Copper.
Dr. Carl V. Moore, St. Louis, Hypochromic Anemias and Iron Metabolism.
Dr. George M. Guest, Cincinnati, Hypoferric Anemia in Infancy.
Conrad A. Elvehjem, Ph.D., Madison, Wis., Physiology of Folic Acid.
Dr. William J. Darby, Nashville, Tenn., Treatment of Nutritional Anemia with Folic Acid.
Dr. William H. Sebrell, Bethesda, Md., B Complex and Anemia.
Dr. Wolfgang W. Zuelzer, Detroit, Megaloblastic Anemia in Infancy.
Dr. Richard W. Vilter, Columbus, Ohio, Vitamin C and Anemia.

OREGON

Dr. Thompson Returns to State Board of Health.—Dr. G. D. Carlyle Thompson, first director of the State Board of Health's maternal and child health program, has returned after four years to head the agency's division of preventive medical services. He resigned in 1943 to take a position with the U. S. Children's Bureau. Dr. Thompson is a graduate of the University of Michigan Medical School, Ann Arbor, Mich., 1928. From 1944 to 1946 he was in the Medical Corps, Army of the United States.

PENNSYLVANIA

New Editor for County Bulletin.—With the September issue of the *Dauphin Medical Academician*, Dr. Lloyd S. Persun Jr., Harrisburg, assumed the duties of editor replacing Dr. William Tyler Douglass, Harrisburg, who has been editor for the past four years. Dr. Persun is a graduate of Temple University School of Medicine, Philadelphia, 1940.

Philadelphia

Personal.—Dr. Valy Menkin, Temple University School of Medicine, attended the sixth International Congress for Cytology in Stockholm July 10, where he was chairman of the section on cell metabolism. He also addressed the fourth International Congress of Microbiology in Copenhagen

Scholarship Established.—Bryn Mawr College is to establish the Anna Howard Shaw scholarship to be awarded to a graduate wishing to study medicine The scholarship was established by income from a $160,000 bequest in the will of Dr. Linda B. Lange, Philadelphia, who died April 24.

Cancer Courses.—The University of Pennsylvania School of Medicine and its hospital, Philadelphia, will offer this fall postgraduate training in the diagnosis and treatment of cancer. The instruction, made possible by a $30,000 allocation from the state's cancer control funds, will consist of three courses of two weeks each on the theory, pathology, diagnosis and treatment of cancer. Courses will be open to all interested physicians.

TEXAS

Dr. Blocker Director of Postgraduate Training.—Dr. Truman G. Blocker Jr., associate professor of surgery since 1944, University of Texas Medical Branch, Galveston, has been appointed professor of plastic and maxillofacial surgery and director of the postgraduate training program at the university. A graduate of the University of Texas Medical Branch, Galveston, 1933, he was a resident surgeon and attending surgeon and plastic surgeon at the John Sealy Hospital, Galveston, and plastic surgeon for the State Hospital for Crippled Children, 1935-1936. From 1936 to 1942 he was an assistant professor of surgery. He served in the war as a lieutenant colonel in the medical corps of the Army of the United States.

WISCONSIN

Community Honors Dr. Jegi.—More than fifteen hundred fathers, mothers and children of the Galeville area gathered to honor Dr. Henry A. Jegi, their physician for half a century. Tribute to the doctor's faithful and efficient service was given by many of his fellow physicians and leaders of the community. Mr. Charles H. Crownhart, secretary of the state medical society, and Roy Regatz, assistant secretary, and over two hundred of the several thousand "babies" delivered by Dr. Jegi were present.

State Medical Meeting in Milwaukee.—The Medical Society of Wisconsin will hold its one hundred and sixth annual meeting October 6-8 at the Milwaukee Auditorium, Milwaukee, under the presidency of Dr. Charles A. Dawson, River Falls. Besides members of the society, those addressing the general scientific sessions are:

Harold G. Wolff, New York, Emotions and Gastric Function.
Anton J. Carlson, Chicago, Some Obstacles in the Path Toward an Optimum Diet.
H. Houston Merritt, New York, Therapy in Epilepsy.
Eugene A. Stead Jr., Durham, N. C., Syncope.
Philip Lewin, Chicago, Treatment in Early Stages of Polio.
Robert M. Zollinger, Columbus, Ohio, Management of the Acute Gallbladder.
W. L. Palmer, Chicago, Functional Disturbances of the Gastrointestinal Disorders.
Milton J. E. Senn, New York, Focal Points in Child Development.
Gordon B. Myers, Detroit, Clinical Use of the Antibiotics.
James H. Bloomfield, Chicago, Management of Late Hemorrhaging in Obstetrics.
Albert M. Snell, Rochester, Minn., Hepatic Diseases.
Donald W. Hastings, Minneapolis, Psychiatry and the General Physician.
Nathaniel G. Alcock, Iowa City, Neoplasm of the Adult Kidney.
Mr. Richard H. Schannen, Fort Wayne, Ind., The Doctor and the Law.

Tuesday morning there will be section meetings on internal medicine, obstetrics and gynecology, ophthalmology and otolaryngology, pediatrics, radiology and surgery. Roundtable luncheons and clinical demonstrations and luncheons will be held each day, and the Loyola University medical alumni in Wisconsin will hold a dinner meeting at the Hotel Schroeder Monday at 6 p. m. The annual dinner will be in the Crystal Ballroom Tuesday evening.

GENERAL

Hodgkins Disease Foundation Drive.—A campaign for $2,000,000 for research will be launched by the Hodgkins Disease Research Foundation October 15. The foundation was formed last March (The Journal, March 8, p. 708) to coordinate separate groups of scientists studying the disease and to focus attention on it.

International Medical Assembly. — The postgraduate school, which is sponsored by the Interstate Postgraduate Medical Association of North America, will be held October 14-17 in the public Auditorium, St. Louis, under the presidency of Dr. James E. Paullin, Atlanta, Ga. A varied scientific program of addresses, clinics and technical exhibits is planned. The registration fee is $5.

Drs. Wall and Grulee Receive Finlay Award.—At the banquet of the first Pan-American Congress of Pediatrics in New York, July 12, Drs. Joseph S. Wall, Washington, D. C., past president of the American Academy of Pediatrics, and Clifford G. Grulee, Evanston, Ill., executive secretary of the academy, were presented with the Carlos J. Finlay Award for their contributions to Cuban sanitation and public welfare.

The March of Dimes and Poliomyelitis.—The National Foundation for Infantile Paralysis reported September 8 that it spent nearly $9,000,000 in the year ended May 31, 1947, most of it fighting record poliomyelitis epidemics, particularly in Illinois, Florida, Alabama, Colorado, California and Minnesota. Basil O'Connor, president of the foundation, said that there were 25,191 polio cases reported, a total exceeded only by the 27,363 cases reported in 1916.

Appointed WHO Chief in Italy.—The World Health Organization Interim Committee has appointed Dr. James A. Farfor, Sanquhar, Dumfries County, Scotland, head of its mission in Italy, succeeding Dr. Gordon M. Frizelle, London, who resigned to become assistant dean of the London School of Hygiene and Tropical Medicine. Dr. Farfor received his M.D. degree from the University of Edinburgh. He has studied at the Charcot Clinic at the Salpêtrière Hospital in Paris.

Academy of Neurological Surgery Meets at Colorado Springs.—The annual meeting of the American Academy of Neurological Surgery will be held at the Broadmoor Hotel, Colorado Springs, Colo., October 9-11, under the presidency of Dr. William S. Keith, Toronto, Canada. Subjects under discussion include Review of Intervertebral Disks, Results of Neurosurgical and Combined Treatment, Brain Tumors in Childhood, and a Report of Five Cases of Psychoses Treated by Restricted Certical Ablation. A symposium on head injuries is scheduled for Friday at 9 a. m. and another on intracranial aneurysms for Saturday afternoon.

Awards for Science Writers.—The American Association for the Advancement of Science has announced the George Westinghouse Science Writing Awards of $1,000 each, one to the writer of the year's best science writing in newspapers and a corresponding one for general magazine science writing. The awards are administered by the association from a grant by the Westinghouse Educational Foundation. This year will mark the first award to science writers for general circulation magazines and the second for newspaper science writers. Entries must have been published in a newspaper between Oct. 16, 1946, and Oct. 15, 1947, or in a magazine between October 1946 and September 1947. Awards will be presented at the annual meeting of the association in Chicago, December 26-31. Deadline for submission of the material is October 6. Address The American Association for the Advancement of Science, 1515 Massachusetts Ave. N. W., Washington 5, D. C.

Fellowships for Study in Argentina.—The Institute of International Education has been asked by the Argentine National Cultural Commission to assist in the selection of two United States graduate students, who will receive fellowships from the commission for ten months' study in Argentina. Fellowships will run from March 1 to Dec. 31, 1948, and will provide round-trip travel plus 5,000 Argentine pesos (about $1,250 at current official exchange rates). The conditions established by the Cultural Commission specify that the recipients of the fellowships shall be graduate students and research workers of recognized standing in the arts, humanities, natural sciences or social sciences, whose work under the fellowship will be of positive benefit to the cultural development of the United States and Argentina. They must be native-born United States citizens over 25 and under 45 years of age and must have a working knowledge of Spanish. Each fellowship holder will be required to have a specific objective and to submit a report every two months as well as a general report at the end of the fellowship period. For details address the Institute of International Education, 2 West 45th Street, New York 27. Applications must be in the hands of the Institute before Oct. 31, 1947.

Disaster Relief Operations.—The most extensive American Red Cross disaster relief operations since 1937 were provided in the three months that ended in early July. Relief expenditures for that brief period were above $4,000,000, which was more than had been expended in either of the two preceding fiscal years. Medical and nursing resources were taxed when lists of injured reached thousands in Texas City, and hundreds at Woodward, Okla. Thousands more in four states required immunization against typhoid by health departments with Red Cross assistance, because of floods. In fifty-five Red Cross shelters opened throughout June to house and feed residents in the flooded areas, Red Cross nursing representatives and disaster nurse reserves supplemented local doctors and nurses in Illinois, Missouri, Iowa and Nebraska. About 48,000 persons were affected by the floods. Among the eleven disaster relief operations in June which required Red Cross aid were tornadoes in Ohio, Pennsylvania and Arkansas; a commercial airliner crash in Virginia; Kentucky flash floods, and floods in central Vermont and southern New York. Cooperating in meeting disaster nursing needs in Kentucky floods was the Frontier Nursing Service. In the first six months of 1947 thirty-three disasters affecting twenty-four states required the services of 425 nurses recruited by the American Red Cross.

Prevalence of Poliomyelitis.—Reports of cases of poliomyelitis for the periods indicated have been received from the division of public health methods, U. S. Public Health Service:

† Figures changed by corrected reports.

‡ Delayed reports: Indiana 33 cases (nonparalytic), July 27 to August 30; Nebraska 2 cases, week ended July 19. Included in cumulative totals.

CANADA

Immunization Week.—Canada's fifth annual National Immunization Week, sponsored by the Health League of Canada in cooperation with local health departments, will be observed October 5-11. The purpose is to call attention to the fact that certain communicable diseases which are taking toll among the nation's children are largely preventable.

Gross Memorial Lecture.—The tenth annual Louis Gross Memorial Lecture will be delivered at the Jewish General Hospital, Montreal, under the auspices of the Montreal Clinical Society October 29 at 8:30 p. m., by Dr. I. Arthur Mirsky, director of the May Institute for Medical Research and associate professor of experimental medicine in psychiatry, University of Cincinnati College of Medicine, Cincinnati. His subject will be "Biology of Metabolic Disease in Man."

LATIN AMERICA

Art Exhibit in Buenos Aires.—An exhibit of fine arts for physicians will be held in Buenos Aires, Argentina, on November 24 of this year. Physicians of Argentina, Brazil, Chile and Uruguay will participate and cordially invite American physicians to participate. The exhibit will be made up of the following three sections: painting, sculpture and photography. Requirements and other information may be obtained from Asociacion Medica de Culture Artistica, Secretaria, Independencia 409-1°. A., Buenos Aires, Argentina, S. A. There will be a special prize for American, Brazilian, Chilean and Uruguayan participants, consisting of a gold medal and a diploma. The inscription for physicians is $5. The items should be sent as soon as possible so that they are received in the headquarters of the Asociacion before Oct. 31, 1947. Physician artists interested in exhibiting are invited to write at once to Mr. A. L. Rose, Mead Johnson & Company, Evansville, Ind., in regard to arrangements for shipping.

FOREIGN

Course on Digestive Pathology.—The thirty-first postgraduate course on Digestive Pathology will be given Oct. 6, 1947 to Dec. 15, 1947 at Escuela de Patologia Digestiva of Hospital de la Santa Cruz y San Pablo in Barcelona, Spain, under the direction of Dr. F. Gallart Monés. The courses will be limited to 30 students: a course of radiodiagnosis, limited to 10 students; a practical course of laboratory, limited to 12 students, and a special course of gastroscopy, limited to 5 students. The price of matriculation is 500 pesetas; matriculation and either radiodiagnosis or gastroscopy, 1,000 pesetas, and matriculation and practical course of laboratory, 700 pesetas.

CORRECTION

The Management of Syphilis.—In the special article in The Journal, Aug. 30, 1947, in the second line of the last paragraph on page 1539, the word "symptomatic" should have been "asymptomatic."

Marriages

Charles Henry Patterson, Lynchburg, Va., to Mrs. Marguerita Goodricke-Cattell Young of Auckland, New Zealand, June 18.

Robert Cunningham Douthat, Long Beach, Calif., to Miss Thelma Lucille Buckley at Las Vegas, Nev., June 6.

Herbert William Park III, Boston, to Miss Frances Bradshaw Little at Greensboro, N. C., July 3.

Louis Albert Packard, Whipple, Ariz., to Miss Grace Darling Winans at Flagstaff June 6.

Raymond S. Mullen Jr., Redlands, Calif., to Dr. Barbara Brady of San Francisco June 19.

Robert Principato, Camden, N. J., to Miss Letitia Anna Orlando of Haddonfield April 26.

Charles W. Young, Kinmundy, Ill., to Miss Linda Elizabeth Rehew in Evanston, Ill., April 12.

Howard Isaacson, Freehold, N. J., to Miss June Lucille Golove of Philadelphia June 22.

Irving Marshall, Trenton, N. J., to Dr. Ethel Geraldine Lawner of Brooklyn June 8.

Edward Stewart Holcomb to Miss Nancy May Eggleston, both of New York, May 3.

John H. Clements, Juneau, Alaska, to Miss Anne Mahoney of Los Angeles April 7.

Deaths

John Herr Musser ⊕ for many years professor and head of the department of medicine at Tulane University School of Medicine, died at his home in New Orleans, September 5, aged 64, of carcinoma of the lung.

Dr. Musser was born in Philadelphia June 9, 1883 and was the sixth member of his family in direct descent to become a physician. In 1908 he graduated from the University of Pennsylvania Department of Medicine in Philadelphia, where he became an associate in medicine in 1914 and assistant professor of medicine in 1920 serving until 1924. From 1912 to 1924 he was physician to the Presbyterian, Philadelphia General and Howard hospitals, all in Philadelphia. At the time of his death he was on the staffs of the Charity Hospital and Touro Infirmary, New Orleans. He had been a member of the Council on Medical Education and Hospitals of the American Medical Association since 1934, vice president and chairman of the Section on Pharmacology and Therapeutics, 1933-1934, chairman of the Section on the Practice of Medicine in 1937-1938 and member of the House of Delegates in 1928. He was for many years a member of the editorial board of the *Archives of Internal Medicine*.

Dr. Musser was a specialist certified by the American Board of Internal Medicine, on which board he had served as a member. He was a member of the Association of American Physicians, American Society of Clinical Investigation and the Association for Research in Nervous and Mental Diseases, American Clinical and Climatological Association, College of Physicians of Philadelphia and foreign corresponding member of the Society of Internal Medicine of the Asociación Médica Argentina, Buenos Aires. He had been president of the Tuberculosis Association of New Orleans, Child Welfare Association of New Orleans, was a fellow and past president of the American College of Physicians, of which he had been a member of the board of regents for many years. He was a trustee of the University of Pennsylvania and at one time president of the Louisiana State Board of Health.

During World War I Dr. Musser served in France as a major in the medical corps of the U. S. Army, and since 1938 he had been a colonel in the medical reserve corps. He received the Alumni Award of Merit of the University of Pennsylvania School of Medicine in 1940. Dr. Musser revised and edited three books, was the editor of *Internal Medicine* and compiled a history of the University of Pennsylvania School of Medicine class of 1908 entitled "Thirty Years After."

At various times he had been editor of the *American Journal of Medical Science*, and at the time of his death he was editor of the *New Orleans Medical and Surgical Journal*.

During recent years Dr. Musser had suffered seriously also with conditions affecting his heart, but with extraordinary courage he maintained his interests and activities to the very end. His contribution to the advancement of medical education and medical science in the United States was notable and will be long remembered.

JOHN HERR MUSSER, M.D., 1883-1947

Clay Ray Murray ⊕ Captain, U. S. Army, retired, New York; born in New York on Aug. 29, 1890; Columbia University College of Physicians and Surgeons, New York, 1912; professor of orthopedic surgery at his alma mater; specialist certified by the American Board of Surgery and the American Board of Orthopaedic Surgery; member of the American Surgical Association, American Academy of Orthopedic Surgeons and the American Association for the Surgery of Trauma; fellow of the American College of Surgeons; served during World War I; entered the medical corps of the U. S. Army as a first lieutenant on Jan. 14, 1918; retired with the rank of captain in July 1920 for disability in line of duty; consulting surgeon, Hackensack (N. J.) Hospital and Sharon (Conn.) Hospital; consultant at St. Joseph Hospital in Far Rockaway; affiliated with the Presbyterian Hospital and Vanderbilt Clinic; author of "Treatment of Injury by the General Practitioner"; contributed chapters to Christopher's "Textbook of Surgery"; died in the Harkness Pavilion June 14, aged 57, of cerebral aneurysm.

John Leonard Kantor ⊕ New York; born in Moscow, Russia, April 12, 1890; Columbia University College of Physicians and Surgeons, New York, 1912; associate clinical professor of medicine at the New York Post-Graduate Medical School and Hospital, Columbia University; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians and the New York Academy of Medicine; member of the American Gastro-Enterological Association and the American Roentgen Ray Society; past president of the New York Gastroenterological Association; served during World War I and World War II; for many years chief of the gastrointestinal clinic at the Vanderbilt Clinic; gastroenterologist and associate roentgenologist at the Montefiore Hospital; gastroenterologist at the Beth David Hospital; consultant gastroenterologist at the Will Rogers Hospital, Saranac Lake, N. Y., National Jewish Hospital in Denver and Sharon (Conn.) Hospital; died in the Mount Sinai Hospital June 26, aged 57, of pulmonary embolism.

David Sanders Moore ⊕ Birmingham, Ala.; born in Clarence, Ala., April 11, 1886; Birmingham Medical College, 1908; member of the Southeastern Surgical Congress, Southern Medical Association and the Birmingham Surgical Society; fellow of the American College of Surgeons; specialist certified by the American Board of Surgery; president of the South Highlands Infirmary; affiliated with Jefferson Hillman Hospital; past president of the Alumni Association of the University of Alabama Medical School; died June 8, aged 61, of coronary occlusion.

Julius Bertram Charles Abels, New York; University and Bellevue Hospital Medical College in New York, 1939; Finney-Howell fellow in medicine at the Memorial Hospital for the Treatment of Cancer and Allied Diseases from 1940 through 1943, when he became assistant attending physician; on the courtesy staff of the Doctors Hospital; consultant in endocrinology at the Meadowbrook Hospital in Hempstead, N. Y.; died June 13, aged 33, of rheumatic heart disease.

Zadok Fowler Atwell, Amsterdam, Ohio; Starling Medical College, Columbus, 1906; veteran of the Spanish-American War and World War I; served on the staffs of the Mercy and Aultman hospitals, Canton; died May 3, aged 81, of coronary thrombosis and arteriosclerosis.

Henry Alden Baughn ⊕ Columbus, Ohio; University of Pennsylvania School of Medicine, Philadelphia, 1917; member of the Columbus Academy of Medicine; died in the Grant Hospital June 9, aged 54, of cirrhosis of the liver.

Ernest I. Bunker, Grantsburg, Wis.; Rush Medical College, Chicago, 1901; past president of the Burnett County Medical Society; served as county coroner and as president of the village and school board; formerly postmaster; for many years local health officer and local physician and surgeon for the Northern Pacific Railway Company; died in the Victory Hospital in Robbinsdale, Minn., June 14, aged 73, of cerebral hemorrhage.

Edward Francis Butler, Mosinee, Wis.; Chicago College of Medicine and Surgery, 1909; member of the American Medical Association; past president of the Ninth Councilor District Medical Society; served as member of the board of trustees and president of the village of Mosinee and when the village became a city became its first mayor; formerly postmaster; died June 5, aged 71, of carcinoma of the prostate.

Adolph Bohumil Cimfel, Scotia, Neb.; University of Nebraska College of Medicine, Omaha, 1939; member of the American Medical Association; first lieutenant in the medical reserve corps of the U. S. Army, not on active duty; on the staff of St. Francis Hospital in Grand Island; died in St. Mary's Hospital, Columbus, June 9, aged 33, of bronchopneumonia and brain tumor.

Fremont Alister Cummins, Los Angeles; New York Homeopathic Medical College and Flower Hospital, New York, 1917; served during World War I; on the staffs of the French, Methodist and Cedars of Lebanon hospitals; died in the Veterans Hospital, Van Nuys, Calif., June 18, aged 53, of massive cerebral hemorrhage.

Paul John Dunn, Pittsburgh; Temple University School of Medicine, Philadelphia, 1929; affiliated with the Mercy Hospital; died June 7, aged 42, of carcinoma of the stomach.

Earl Elvin Evenson ⊕ Wittenberg, Wis.; Northwestern University Medical School, Chicago, 1927; died in Wausau June 9, aged 46, of gastric carcinoma.

James Louis Fagan ⊕ New Brunswick, N. J.; University of Louisville Medical Department, 1914; fellow of the American College of Surgeons; served during World War I; on the staffs of the Middlesex General Hospital and St. Peter's Hospital, where he died June 7, aged 55, of myocardial infarction.

Edward Ambrose Flinn, Neodesha, Kan.; Miami Medical College, Cincinnati, 1882; died May 25, aged 90, of cerebral hemorrhage.

Alfred Davis Henkel, Winchester, Va.; University of Pennsylvania Department of Medicine, Philadelphia, 1887; member of the American Medical Association; died May 27, aged 86, of thrombosis.

David Ralph Landau, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903; member of the American Medical Association; died in the Michael Reese Hospital June 14, aged 71, of coronary occlusion.

William B. McClure, Lexington, Ky.; Louisville Medical College, 1883; for many years treasurer and past president of the Kentucky State Medical Association; served as a member of the county board of education; died June 10, aged 89, of arteriosclerosis.

Robert Louis McCorkle, Atlanta, Ga.; Emory University School of Medicine, Atlanta, 1941; member of the American Medical Association; interned at the Georgia Baptist Hospital; served during World War II; electrocuted in Gaffney, S. C., June 15, aged 30, when his automobile struck an electric pole.

Benjamin F. Mallory, Arlington, Kan.; Missouri Medical College, St. Louis, 1897; member of the American Medical Association; on the visiting staffs of the Grace and St. Elizabeth's Hospital in Hutchinson; died June 3, aged 76, of carcinoma of the pancreas.

Charles Fowler Merrill, Highland Park, N. J.; College of Physicians and Surgeons, Baltimore, 1902; member of the American Medical Association; served during World War I; on the staffs of the Middlesex Hospital and St. Peter's Hospital, New Brunswick, where he died May 29, aged 71, of organic heart disease.

John Charles Miller, Union City, Mich.; Kentucky School of Medicine, Louisville, 1893; Bellevue Hospital Medical College, New York, 1894; served during World War I; died in the Veterans Administration Hospital in Fort Custer June 11, aged 81, of pulmonary infarction and generalized arteriosclerosis.

Robert Hugh Monahan, International Falls, Minn.; Minneapolis College of Physicians and Surgeons, medical department of Hamline University, 1906; member of the American Medical Association; served with the British Army during World War I; affiliated with St. Barnabas Hospital, Minneapolis, and the Northern Minnesota Hospital; died in the Passavant Memorial Hospital, Chicago, June 3, aged 76, of cerebral hemorrhage.

Porter B. Orr, Asheville, N. C.; Jefferson Medical College of Philadelphia, 1901; member of the American Medical Association; for many years on the staff of the Asheville Mission Hospital; died June 6, aged 72, of cerebral thrombosis.

Edward Jennings Overstreet, Baxley, Ga.; Emory University School of Medicine, Atlanta, 1924; member of the American Medical Association; served during World War I; member of the board of education; died June 1, aged 48, of acute nephritis.

James Tressillian Padgett, New York; University Medical College of Kansas City, Mo., 1900; University of Louisville (Ky.) Medical Department, 1904; served on the staff of the Lutheran Hospital; died June 10, aged 71, of carcinoma of the lung.

Charles Ector Patterson ⊕ Tucson, Ariz.; University of Maryland School of Medicine, Baltimore, 1903; specialist certified by the American Board of Otolaryngology; fellow of the American College of Surgeons; served as a member of the staff, Desert Sanatorium of Southern Arizona and Institute of Research, Southern Methodist and Comstock Children's hospitals and St. Luke's-in-the-Desert Sanitarium; on the courtesy staff of the St. Mary's Hospital and Sanatorium; died June 10, aged 70, of coronary thrombosis.

Harvey Edwin Ramsey, Phoenix, Ariz., Cleveland-Pulte Medical College, 1896; Western Pennsylvania Medical College, Pittsburgh, 1900; member of the American Medical Association; on the staff of the Suburban General Hospital in Pittsburgh; died in the Good Samaritan Hospital June 7, aged 78, of pneumonia.

Thomas H. S. Roe, Rock Springs, Wyo.; Washington University School of Medicine, St. Louis, 1906; member of the American Medical Association; served as mayor; died suddenly in the Wyoming General Hospital, May 12, aged 66, of angina pectoris.

Paul Griffith Sanger ⊕ Santa Rosa, N. M.; University of Oklahoma School of Medicine, Oklahoma City, 1931; member of the Oklahoma State Medical Association; formerly a resident in neuropsychiatry at the Eastern Oklahoma State Hospital in Vinita; died in Tucumcari Hospital, Tucumcari, May 24, aged 45, of pneumonia following a lung abscess.

Norman Brown Saunders, Mount Vernon, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1900; member of the American Medical Association; on the consulting staff of the Tarrytown Hospital in Tarrytown, New Rochelle (N. Y.) Hospital and the Grasslands Hospital in Valhalla; died June 6, aged 71, of pneumonia.

Charles Slater Shriver ⊕ Columbus, Ohio; Starling Medical College, Columbus, 1906; on the staff of the Mount Carmel Hospital; died June 10, aged 66, of cerebral hemorrhage and coronary thrombosis.

William W. Simms, St. Louis; American Medical College, St. Louis, 1912; died in the Barnes Hospital June 9, aged 74, of complications due to injuries received in an automobile accident in March.

John M. Smith, Poplarville, Miss.; Medical Department of Tulane University of Louisiana, New Orleans, 1893; died June 4, aged 79, of arteriosclerotic gangrene.

Ellen A. Starr Souder, Rockwell City, Iowa; Chicago Homeopathic Medical College, 1882; died May 17, aged 89, of coronary thrombosis.

William Steffens, Baldwin, N. Y.; Ernst-Moritz-Arndt Universitat Greifswald Medizinische Fakultät, Greifswald, Prussia, 1888; member of the American Medical Association; died May 20, aged 84, of diabetes mellitus, renal calculi and hypertensive heart disease.

Charles J. Stettheimer, Denver; University of Colorado School of Medicine, Denver, 1932; member of the American Medical Association; specialist certified by the American Board of Pediatrics; assistant in pediatrics at his alma mater; affiliated with the Children's Hospital, where he died June 11, aged 42, of pericarditis.

Jerome Aloysius Strack, South Orange, N. J.; St. Louis University School of Medicine, 1938; member of the American Medical Association; served in the medical corps of the U. S. Naval Reserve for two and a half years during World War II; on the staffs of St. Michael's Hospital in Newark and St. Mary's Hospital in Orange, where he died June 11, aged 34, of diabetes mellitus, acute nephritis and acute myocarditis.

Samuel Lanier Stringfield ⊕ Waynesville, N. C.; Jefferson Medical College of Philadelphia, 1905; past president of the Haywood County Medical Society; member of the staff of the Haywood County Hospital, of which he formerly had been chief of staff; died June 11, aged 66, of rheumatic heart disease.

John Emil Swanson, Sioux City, Iowa; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1899; member of the American Medical Association; served during World War I and as county coroner; died in the Swedish Hospital in Minneapolis June 1, aged 74, of arteriosclerosis and hypertension.

Harold Benjamin Thompson, Seattle; Rush Medical College, Chicago, 1906; specialist certified by the American Board of Radiology, Inc.; member of the American Medical Association, Radiological Society of North America and the American College of Radiology; on the staffs of the Children's Orthopedic Hospital and the Seattle General Hospital, where he died June 16, aged 64, of coronary disease.

Hubert King Turley ⊕ Memphis, Tenn.; Jefferson Medical College of Philadelphia, 1914; associate professor of urology at the University of Tennessee College of Medicine; specialist certified by the American Board of Urology; member of the Southeastern Surgical Congress and the American Urological Association; fellow of the American College of Surgeons; served during World War I; on the staffs of the Baptist Memorial, John Gaston and Methodist hospitals; died June 19, aged 55, of cerebral thrombosis and arteriosclerosis.

Cilie Hirschfield Weichsel ⊕ Teaneck, N. J.; College of Physicians and Surgeons, Boston, 1904; member of the Medical Society of the State of New York; died May 26, aged 69, of carcinoma of the transverse colon.

Elmer E. Welsh, Eaton, Ohio; Jefferson Medical College of Philadelphia, 1882; died June 2, aged 85, of chronic myocarditis.

A British Commonwealth Medical Council

In his presidential address at the annual meeting of the British Medical Association Sir Hugh Lett stated that the association had been exploring means whereby medicine throughout the commonwealth and empire can be advanced and can play its part in strengthening those bonds which mean so much and which in years to come may prove a pattern to the whole world. They had long been anxious that their relations with their colleagues overseas should be developed and become closer still, and this feeling was shared by them. To this end the association believed that greater opportunities should be provided for personal contact, so that views could be exchanged and difficulties discussed. In no other way could they have a complete understanding of each other's problems, nor could anything do more to strengthen relations than the development of personal friendships. The council of the association had therefore decided that the affiliated and daughter associations in the commonwealth should be invited to cooperate in establishing a British commonwealth medical council. Each would appoint its own direct representatives, and it was suggested that the meetings should be held in the principal centers overseas as well as in London. The objects of this council would be (1) to develop and maintain closer contact between practitioners in the United Kingdom and in the dominions and between practitioners in the various dominions; (2) to advance the status of British medicine; (3) to stimulate discussion and exchange of advice on matters of common interest; (4) to promote an exchange of professional facilities.

It is also proposed to establish an empire medical advisory bureau at the House of the British Medical Association for giving advice and help to those who come here from the commonwealth and colonies for postgraduate or undergraduate study. The work of the bureau will not be limited to giving advice on academic matters. It is intended to help socially in various ways, such as by assisting men to find accommodation and putting them in touch with their British colleagues.

The World Medical Association

The president went on to discuss a still further stage of professional cooperation. Last September an international medical conference was held in London on the initiation of the British Medical Association, and the World Medical Association was formed. Its first annual meeting will be held in Paris in September, and the delegates of at least thirty countries are expected to attend. Its objects are (1) to provide closer ties among national medical organizations and among doctors of the world by personal contact and other means in order to assist all the peoples of the world to attain the highest level of health; (2) to study the professional problems of different countries; (3) to organize an exchange of medical information; (4) to establish relations with the World Health Organization. This represents governments, while the association represents the medical associations of the world.

National Health in the Transition from War to Peace

The report of the Ministry of Health for the year ended March 31, 1946, which has just been presented to Parliament, sums up the health position in the difficult transition period from war to peace. During 1945 the health position was maintained at the same high level as during the six years of war. The return of so many soldiers and prisoners of war, often weakened and including many convalescents from and carriers of every known infectious or tropical disease, set a great problem, which was triumphantly solved. Thanks to the watchfulness of the intelligence and epidemiologic sections of the ministry and the alertness of the health officers, such dangerous invaders as typhus, smallpox and malaria were given little chance to spread. Apart from the general maintenance of health, 1945 was noteworthy in two respects: the mortality of children reached new low levels, far lower than those of 1939, which was mainly a prewar year; the infant mortality (46 per thousand live births) was well below any year preceding 1945. The maternity mortality (1.80 per thousand total births) was the lowest recorded. The civilian death rate, which included deaths due to war operations, was 12.6 per thousand below the average of the three preceding years.

Other satisfactory figures were the extraordinary reduction in recent years of the mortality from measles and scarlet fever in those under the age of 15, the country's good fortune during the war years in the mildness of influenza, the success in preventing enteric fevers and the decrease in diabetes and pneumonia mortality. New low records were set of both notifications and deaths from diphtheria (18,596 and 722 respectively). Mass immunization against diphtheria was introduced in 1940, with deaths from the disease each year since 1941 recorded as 2,641, 1,827, 1,371, 934 and 722. It is estimated that at the end of 1945 58 per cent of the children under 15 were immunized. The downward trend of the mortality from tuberculosis has been resumed after the rise in the war years. Mass radiography of civilians shows that between 3 and 4 persons per thousand examined had previously unsuspected but active pulmonary tuberculosis. The number of deaths from cancer was 73,753, an increase of 2,065 over 1944. The active research on the disease, which has been going on for many years, so far has been unable to stem the increase.

Foreign Doctors to Be Granted Permanent Registration

The war brought to this country a number of doctors from all parts of the world, many of them fleeing from Nazi persecution, who under the ordinary law could not be admitted to the British Medical Register on the strength of the qualifications obtained in their own country. But, because of the shortage of medical man power to meet the demands of the war, it was evident that these foreign doctors would be a valuable help. The law was therefore amended, granting temporary registration to those who served in the Allied forces or undertook certain specified kinds of medical employment. Citizens of the United States were given registration solely on the strength of their American diplomas. We were fortunate in having among the temporarily registered doctors a substantial proportion of distinguished specialists. The number of the temporarily registered in February 1946, when temporary registration ceased, is estimated as between 3,500 and 4,000, but this included a large number of doctors in the American and Canadian forces who have since left the country. It is estimated that the number now is between 1,500 and 2,000, including Polish doctors who are registered under the Polish Resettlement Act.

The government has had to consider what is to happen to the foreign doctors when temporary registration comes to an end next December. They have decided that those who have rendered useful service to this country and desire to remain should be allowed to practice here. Many of them are elderly and it would hardly be reasonable to require them to study for British qualifications, even if facilities were available in the British medical schools. A bill has therefore been prepared and has passed its first reading empowering the Medical Council to grant permanent registration, which will be accorded only on evidence of character, education and satisfactory service, so that there will be no lowering of the standard [illegible] by the Medical Council.

Control of Films Dealing with Medical Subjects

A number of films dealing with medical problems have recently been shown. Their influence on the public has been at times instructive and salutary and, at other times, harmful and even tragic. The National Academy of Medicine has been led to consider this problem by two observations presented at one of its last meetings by E. Redslob (Strassburg) and J. Sedan (Marseilles):

A girl 14 years of age, physically sound, saw a motion picture about a blind girl operated on for cataract, who drowned herself afterward for sentimental reasons. Thereafter this young girl presented psychic troubles and a hysteric amaurosis; a psychiatrist succeeded in curing her within a comparatively short time.

A girl aged 19, seriously myopic, was admitted to the hospital for treatment of a detached retina; she had previously lost one eye through the same trouble and was to be operated on in a few days. The girl attempted to commit suicide by taking a barbituric acid derivative, which left her hovering between life and death for eight days. Eventually, the operation was successfully performed and the girl regained four tenths of her vision. The idea of committing suicide had been suggested to her by a film showing a young woman with double detachment of the retina, who was told by an eminent ophthalmologist that she would become blind (a false prognosis), and who committed suicide.

Both ophthalmologists emphasize that the same danger of the nefarious influence of certain films exists in the field of general surgery as well as in other branches of medical practice.

The National Academy of Medicine has expressed the wish that "in the future, the film censorship, before taking its decision and in special cases, take the opinion of qualified medical and surgical technicians, who, thanks to their expert advice, will prevent the recurrence of such incidents, which are most unforgivable as they are connected with the exploitation of material interests."

First Cases of Tularemia in France

Violle in 1930, Rochaix and Maurin in 1932 and Brumpt in 1937 drew attention to the possible appearance of tularemia in France. Richez suspected its presence in 1938, but no bacteriologic proof could be obtained. In March 1946, at a meeting of the Medical Society of the Paris Hospitals, Girard, Blass and Ely presented the first observation on 2 patients who caught the disease when skinning a hare. Their children, who ate the hare, remained unaffected. Lately, Professor Girard of the Paris Pasteur Institute has reported the existence of two different seats of tularemia (2 cases in the Gironde and 1 in the Dijon district). The first case of animal tularemia was reported to the Veterinary Academy last March. At one of the latest meetings of the Medical Society of the Paris Hospitals René Martin, P. Mercier and R. Peret reported a case of human tularemia due to the bite of a wild boar. This is noteworthy on account of the mode of contamination, which is exceptional, and also from the epidemiologic point of view, as the wild boar is an animal which moves with great rapidity and is therefore capable of transporting the disease to a distance of hundreds of kilometers. The authors say that neither penicillin nor sulfonamides drugs had curative action on the disease. As regards prophylaxis, there are several ministerial orders of 1937 and 1938 prohibiting the importation from infected countries of living or dead animals sensitive to the disease; on the other hand, by a decree of the 19th of July 1947 of the Ministry for Public Health, human tularemia is added to the list of diseases that must be declared.

New Method of Hematotherapy

Claude Bernard insisted on the primordial role of the reserve substances in the phenomenon of cellular nutrition and regeneration. Portier and Jolly emphasized the propriety of nutritional reserves of the lymphocytes in deficient, anemic organs or in those in the course of growth. P. Brocq and T. Stephanopoli (Glacière and Hôtel-Dieu hospitals) have shown by their work that red blood cells have also a metabolic function and that, on account of their exceptional content of iron, other cellular constituents and specific proteins, they represent real nutritional reserves. The authors have ascertained this capability in the treatment of wounds, especially of those in which circulation is deficient, by providing the atonic tissues with red blood cells in the form of powder. The powder of hematids, from the blood of the patient or of one of his relatives, is obtained by drying the red blood cells at the temperature of the body after a previous separation of the other elements of the blood and a suitable fixation in alcohol. With the powder of hematids, the tissues start proliferating again by means of a phagocytic activity, cicatrization is accelerated and the peripheral circulation improves rapidly. Moreover, the authors have used total blood and isolated hematids in the treatment of thrombophlebitis, thus showing the superiority of the latter treatment, especially as regards the restoration of neurohumoral equilibrium. The isolation of the red blood cells is obtained after sedimentation in a citrated medium, complete decantation of the supernatant liquid and elimination of the superior layer of the sediment; at the time of use, the hematids are emulsified in an isotonic and new serum. The authors think that this isolation of the red blood cells, which are kept for twenty-four to forty-eight hours in a preserving medium to produce the growth of microcytes with a high peroxidase intake, still definitely increases the therapeutic action.

Death of Professor Louis Texier

Professor Louis Texier, a surgeon well known as the Chief of the Lyons School, whom a large number of surgeons of this city consider as their master, died at 76 years of age. A disciple of Cordier, Poncet and others, he was promoted to surgeon to the Lyons Hospitals in 1900 and became a university professor in 1901. In 1914 he was appointed professor of surgical clinics and succeeded Poncet. As a practitioner and a professor, he particularly devoted himself to postoperative treatment and, to foster this aim, attached an expert clinician to his surgical staff. Moreover, he considered that the perfection of the operation derived from the attention given to the preliminary observation of the patient. Among his many works are those on gastric surgery, gastroduodenal hemorrhage (for which he proposed jejunostomy in 1908) and the pseudoneoplastic form of appendectomy in aged patients. His works on the surgical treatment of uterine fibromas are still of value. In 1920 he was elected president of the Congress of Surgery. He was a national associate to the Academy of Surgery.

Miscellaneous

At a general meeting of the Association for the Paris Swiss Hospital in Paris it was decided by unanimous vote to establish a Swiss Hospital in Paris, which will comprise a clinic for surgery and general medicine.

At the Paris Pasteur Institute, Professor René Dubos of the Rockefeller Institute of New York read a paper on new methods of culture of the Bacillus tuberculosis and their application to the study of the virulence of the organism.

Congress of Clinical Biology

The French Society of Clinical Biology has organized the first International Congress of Clinical Biology under the presidency of Professor Polonowsky, to take place November 20-22.

BELGIUM

(From Our Regular Correspondent)

Aug. 8, 1947.

Twenty-First Session of the Medical Days of Brussels

The twenty-first session of the Journées médicales of Brussels came to an end in an atmosphere of great enthusiasm. All the foreign delegations were profoundly impressed with the atmosphere of work and prosperity which at present prevails in Belgium. Dr. Loicq succeeded Dr. Beckers in the important function of secretary general and as the organizer of this truly international convention.

Scientific Humanism

The opening address was given by Professor O. Weill, president of the Journées médicales. It was a manifestation of scientific humanism of high quality. He drew the balance sheet for our generation and affirmed that each year will find a new strategy and a new scientific tactic. At present as it concerns medicine, the pastoral controversies have fallen and one finds oneself confronted with fact that is considered as acquired knowledge. He reviews successively the discovery of antibodies, of allergy, the notion of the sympathetic pharmacology and the application in this sphere of the sympatheticotonics, the vagotonics, without counting the possible operations. He mentions the vitamins, the endocrines, the synthetic hormones, the sulfonamides and penicillin; and finally the sensational intrusion of physics. There are the new technics ultrafiltration, ultracentrifugation, the rays and, crowning all, the nuclear physics. And here we have to consider the infinitely small, which is also the infinitely powerful. The isotopes appear. Henceforth one creates new chemical entities: the transuranic elements. This creation is for good and for evil. At present one is confronted with more than a hundred models of the atom, of which some are no longer geometric reality but constitute simple mathematical entities. Henceforth it is to be this mobility, this oscillation of ideas which will constitute the characteristic of contemporaneous science.

Conferences and Demonstrations

Numerous conferences and demonstrations drew a great influx of participants. There was (1) that of Professor Levaditi, concerned with the mechanism of antibiotic action of penicillin and streptomycin in experimental infections produced by various pathogenic germs. Then there was (2) the theory of primary calcification, which was discussed by Dr. Marcel Dallemagne. One of the best attended conferences was (3) that of Dr. Albert Claude of the Rockefeller Institute, which was concerned with the electron microscope and its application to normal and cancerous cells. Claude presented views showing twin microblasts in the midst of cancerous cells, the study of which is certain to change the nature of cancerology. The conference of Dr. L. D. Erland, professor of surgery at the University of Groningen, (4) took up the problem of transthoracic esophagectomy for cancer of the esophagus. The illustrating projections showed extraordinary surgical results, notably as they concern the establishment of a thoracic stomach. A very curious conference (5) was devoted to the physical pains resulting from moral conflict. It was held by Dr. Henri Flournoy of the University of Geneva, who showed a novel application of treatment with psychoanalysis.

Occupational Reeducation of the Tuberculous

The Belgian Society of the Scientific Study of Tuberculosis has devoted a session to the different points concerning the occupational reeducation of tuberculous patients. Courtois and Gyselen reviewed the problem in its entirety. The occupational reeducation in all sanatoriums must be an integral part of the treatment of the tuberculous with an arrested process.

What good will it be to devote so much effort to the treatment of tuberculous patients if the ultimate reclassification is lost sight of? The resumption of work must be the preoccupation of the patient and his physician. A special organization has been created for this, the social service, which, subordinate to the medical directives, will aid convalescents to resume in society a role in keeping with their capacity for work, with their aptitudes, their tastes and their personal and family interests.

Thus it is necessary to envisage two periods: (1) the complement to the sanatorium cure and (2) the transition between the sanatorium and normal active life. The first is realizable anywhere at little expense; it involves only nonremunerative work under medical supervision (horticulture, stock raising, care of patients and diverse maintenance work). The second implies the availability of good workshops where medical influence must not cease to be exercised. In these workshops the work can be carried out according to two principles: industrialized and immediately remunerative work or educative work more interesting from the professional point of view of the convalescent but infinitely more costly; this type of organization cannot be developed without the intervention of public powers.

Ultimately and from most points of view, artisan work done in the domicile will be that which is best for the cured tuberculous patient or for the one whose process is arrested; it is often the best utilization of the partial work capacity, but modern society has hardly any place for this. It is also necessary that the cured patient do the work which best conforms to his capacities and which is best paid.

Medical Examination of Chauffeurs

In the *Moniteur* there appeared a decision bearing on the regulation of the selection and medical supervision of chauffeurs of public service busses and cars and of other passenger motor vehicles charging fare. This regulation says especially that the medical examination shall determine the absence of disease or of all mutilation, malformation or infirmity of a nature to hinder or impede, even temporarily, the normal handling of the vehicle as well as of ordinary repair work. This medical examination also involves a psychotechnical test appropriate to the functions of a driver of motor vehicles. The disqualifying disorders and anomalies as well as the details of the psychotechnical test are determined conjointly by the minister of public health and family and by the minister of communications. The administration of the health service will establish a file for each candidate, to be kept in its archives. The medical information in this file may be communicated only to the candidate's physician.

The Profession of Pharmacist

On the occasion of the celebration of the centennial of the School of Pharmacy at the University of Brussels, Professor Wattiez, vice president of the school of medicine and pharmacy, delivered a dissertation on "Pharmaceutical Instruction and the Profession of the Pharmacist." The immediate aim of such instruction is evidently the training of the practicing pharmacist. The pharmacist finds himself in a paradoxical situation, which obliges him to dispense under his own responsibility medical products the majority of which are specialties and which therefore escape his examination. The Belgian pharmaceutical industry is not subject to any control on the part of the state and is not even obliged to operate with competent persons having university training.

To remedy this curious situation, Professor Wattiez proposes to recognize two types of pharmacists, the apothecary pharmacist and the industrial pharmacist, to divide the responsibility involved in the preparation and the delivery of medicaments. He declared himself also in favor of the apportionment of apothecary pharmacists in accordance with the density of the population and proposed that the profession should be practiced only by persons who have completed their twenty-fifth year.

The administrative council of the University of Brussels has approved the creation by a school of pharmacy of a special license in the pharmaceutical sciences intended to develop pharmacists desirous of devoting themselves to laboratory work. This license comprises several sections: (1) biologic and bromatologic analyses, (2) toxicologic chemistry, (3) industrial pharmaceutic chemistry and (4) alimentary industrial chemistry. This new instruction requires the collaboration of the university and industry. Wattiez is of the opinion that this collaboration can be profitable for both.

Superior Council of Physical Education and Sports

Prof. Dr. Vanderwael believes that the development of sports in Belgium merits the attention of public authorities. Under governmental direction physicians licensed in physical education should control the physical activities of all the school population, of adolescents and of adults. He thinks that the practice of physical education in schools according to a program and generally adopted directives would lead to fewer excesses in sports among young people. Youth likes to spend its energies, and it is necessary to give it an opportunity to prepare itself by gymnastics and to develop itself by sport and games. With the proper control there will be less regrettable adventures. He favors the extension of medical inspection to all and hopes for the full time employment of physicians.

Collaboration Between Professor and Students

The Faculty of Medicine of Liége has established a commission charged to develop means of contact to be established with the delegates of the students with a view of joint study of questions relating to the organization of the medical and pharmaceutical studies: programs, length of courses, time tables, organization of the clinical instruction, coordination between the different instructions, intellectual and physical health of the students. This committee has been wise in obtaining the opinions of former students, who are best fitted to distinguish between the essential and the secondary, between the permanent and the ephemeral. This step approaches the staff-student committees which function in several British and American universities.

ITALY

(From Our Regular Correspondent)

FLORENCE, July 17, 1947.

The Mechanism of the Beneficial Effect of Electroshock Treatments

Professor Ugo Cerletti, director, Neuropsychiatric Clinic, University of Rome, reported to a large audience at the Health Institute in Rome the results of experiments to clarify the mechanism of the effect of electroshock. Some years ago Professor Cerletti suggested the use of intensive but highly rapid electrical discharges for the treatment of certain psychoses, particularly of melancholia.

In his studies of the manner in which electroshock produces its beneficial effect, Cerletti became convinced that the curative factor is not represented by the electricity but by the epileptic attack resulting from the short electric shock. Cerletti says that the epileptic attack or coma is an extreme risk to which the nervous system is submitted and, by the effort of overcoming it, extreme biochemical reactions of a defensive and vitalizing character are provoked. He submitted groups of swine to a variable number of electric shocks and obtained from the brains of the animals specific extracts which he collected in vials with the intention of using them therapeutically. For control purposes he also prepared extracts from the brains of swine which did not receive the electric shock treatment.

After both series of extracts were found to be innocuous to himself and to many other persons, he studied the effect of those injections in melancholia, a disease which responds best to electric shock. While extracts from the brain of animals not submitted to electroshock produced no change in the morbid condition of patients to whom they were administered, important changes ensued from the injections of the extracts of the shocked brains. Rapid recovery resulted in several patients; others presented unquestioned improvement; in others the disease remained unchanged. In almost all the cases with a favorable course the most typical effects consisted in the cessation of the obstinate insomnia and anxiety state, and improvement of the behavior. Without drawing definite therapeutic conclusions from this experience, it seems that the shocked brain differs "humorally" from the nonshocked brain.

In carrying his investigations further, Cerletti attempted to specify the defensive power of the substances obtained from the shocked brain of swine, and he selected for experimentation a disease of the brain with a definite and fatal course: rabies.

These experiments convinced him not only that the brain treated with electroshock contains substances which do not exist in the normal brain, but that these substances have a high defensive power against some morbid factors. Cerletti has coined the term "acroagonine" for these substances, or substances resulting from extreme effort (struggle).

Social Aspects of Tuberculoid Leprosy

Dr. Nelson Souza Campos, chief of the leprosy department of São Paulo, in collaboration with Drs. A. Rotenberg and L. M. Bechelli, pointed out some social aspects of leprous patients in a paper read before the Sociedade Paulista de Leprologia. They called attention to the favorable prognosis in cases of tuberculoid leprosy which show a positive Mitsuda lepromin reaction. The stigmatizing word "leprosy" is used for those patients with the worst possible effect on their morale. While in the past all patients with leprosy had to be segregated, now with a better knowledge of the epidemiology of the disease the tuberculoid patients are allowed to remain free from isolation and still later even from severe control or treatment. A further step would be to prevent the moral shock and social ruin from the diagnosis of "leprosy." A completely different name should be found as a substitute. In the meantime the leprosy department of São Paulo has been following lately the policy of recording such persons only as "suspects" and keeping them under minimum control.

New Concept of Hepatic Disease

The general concept of liver and biliary tract diseases in which there are no well defined and constant lesions is changing rapidly, according to a paper read by Dr. João Montenegro before the surgical branch of the Associação Paulista de Medicina. The right upper abdominal quadrant pains and the symptoms of dyspepsia, long ago supposed to be due to liver insufficiency and later on thought to be due to chronic noncalculous cholecystitis, are, in the majority of cases, due to irritation and dyskinesia of the duodenum or hepatic flexure of the colon or to both; they are brought forth by foodstuffs which are not well tolerated. The dominating idea ought to be that of dyskinesia of the digestive canal elicited by foodstuffs on intestines irritated by unknown causes but which may perhaps be allergy in a wider sense, psychosomatic changes, perturbed biochemical or endocrine functions, vagosympathetic changes of neuralgic type or entities of that sort. Only when the history, physical examination, cholecystography and duodenal intubation, correctly carried on, show clearly an organic lesion, will operation be indicated. Otherwise treatment is clinical on the basis of specially adapted diet for each case.

Correspondence

LEUKEMIA IN RADIOLOGISTS

To the Editor:—In the article on "The Longevity and Mortality of American Physicians, 1938-1942" (The Journal, August 9). Dublin and Spiegelman state that "the greatest excess in the mortality of physicians is found from leukemia, their death rate from this cause being 175 per cent of that for white males in the general population."

In a statistical study on "Leukemia in Radiologists" (*Radiology* **42**:275 [Sept.] 1944) I pointed out that the incidence of leukemia deaths in nonradiologic physicians in the fifteen year period between 1929 and 1943 inclusive was 0.44 per cent. The incidence of leukemia deaths in adult white men above the age of 25 (and also above the age of 30) was 0.33 per cent of deaths with the cause given in the biennium 1939-1940, according to the figures of the U. S. Bureau of the Census (3,932 leukemic deaths in 1,172,036 above the age of 25 in white males). This makes the increased incidence in nonradiologic physicians 133 per cent, which is less startling than 175 per cent. However, when the situation of the radiologists is examined, a most astounding difference is found. As I pointed out, the incidence of leukemia in radiologists is over ten times as great as in nonradiologic physicians, and this difference is quite significant from a statistical analytic point of view.

My follow-up since the period covered in this report shows the same trend and will be the subject of a subsequent report. In view of this decided difference of the incidence of leukemia in radiologists, it does not seem improbable that the 33 per cent increase in incidence of leukemia in nonradiologic physicians above the general adult white male incidence may in large part or perhaps wholly (barring better diagnosis in physicians) be explained by that not inconsiderable segment of nonradiologic physicians who use fluoroscopes, x-ray machines and radium in their practice, many of whom do *not* take proper protective precautions. It takes only an additional three nonradiologic physicians throughout the country to die of leukemia in a year to raise the incidence from 0.33 per cent to 0.44 per cent! The implications are plain. It behooves any one using any of the aforementioned forms of radiant energy to employ standard measures for self protection, even though these cannot necessarily afford complete protection. The second implication is that, if the radiologists who developed leukemia employed these standard measures of self protection routinely, then these measures are insufficient to protect against this occupational hazard.

Herman C. March, M.D., Philadelphia.

CLINICAL AID TO ALASKA

To the Editor:—I am writing in regard to the team of five men who recently toured a portion of the Territory of Alaska. The object of this trip was to gain an impression and summarize some of the most urgent medical needs of the people of Alaska.

On about April 1, 1947 I accepted the position of Orthopedic Surgeon for the Territory of Alaska with the object of summarizing the orthopedic problem of Alaska and establishing and operating a small orthopedic center in Sitka. Distances and lack of communication as well as limited funds plus the high rate of pulmonary tuberculosis, which in turn contributed to a large number of cases of involvement of the bone, presented a problem which seemed almost overwhelming. All of us realize that we are in urgent need of help from the persons within the territory as well as from those in the states. It was also an obvious fact that reports from persons within the territory would not be as important as those from disinterested groups as persons who might not have a mercenary reason for asking aid for Alaska.

There have been many visitors to the territory. In fact, so many of these groups have been through on inspection tours that it has become somewhat of a joke about persons who come to Alaska simply to see the country and catch a few fish. The residents of the territory look on these visitors with a jaundiced eye.

It was therefore a welcome change to meet the men of the group who recently visited here. They were obviously well chosen. All reports indicate that they were hard workers. They performed an incredible amount of work in the short period of time they were here at Sitka. I met them at a luncheon at the Rotarian Club and have also talked to a great many of the residents in this area since they departed. The opinion was unanimously favorable, and I believe that the American Medical Association is to be congratulated on the physicians selected and the work that this group of men accomplished while in Alaska. The members of this group, whose names are Drs. George Milles, Arthur Bernstein, Joseph Silverstein, Harry E. Barnett and Jack Fields, have left us with increased hope that the public and the authorities in the United States will become more cognizant of our need for help.

Philip H. Moore, Orthopedic Surgeon,
Mt. Edgecumbe Hospital,
Sitka, Alaska.

THE LONGEVITY AND MORTALITY OF AMERICAN PHYSICIANS

To the Editor:—The article "The Longevity and Mortality of American Physicians, 1938-1942" in The Journal, August 9, by Dr. Dublin and Mr. Spiegelman is impressive and pertinent. These authors have written convincingly on an all important subject and one, according to the report, of special interest to physicians. The writers have apparently proved that coronary diseases are 80 per cent more frequent in male physicians than in a comparable group of men in the average population. It is serious enough to know that heart diseases are the main cause of death in this country and that coronary diseases are the most significant of these, but now we learn that physicians suffer from coronary diseases to a greater degree than others. However, I believe this can be remedied.

There are two chief divisions of coronary diseases, as my colleagues and I have shown. The classic "acute coronary occlusion" is a disease characterized by sudden, complete, irreversible occlusion of the coronary lumen. "Acute coronary insufficiency" is a deficiency of the coronary circulation due to discrepancy in the demands of the myocardium and its available blood supply. It is usually transient and reversible, although its effect on the myocardium may be permanent. Angina pectoris is a transient episode of acute coronary insufficiency.

In acute coronary occlusion there is no direct means of prevention and treatment. It is as common in the sedentary person as in the laborer (Master, A. M.; Dack, Simon, and Jaffe, H. L.: The Role of Effort, Trauma, Work and Occupation in the Onset and Subsequent Course of Coronary Artery Occlusion, *M. Ann. District of Columbia* **10**:79 [March] 1941). During the attack the treatment is primarily symptomatic, and the specific treatment is for the complications. Quite the contrary holds true in acute coronary insufficiency. It is generally preventable and can be specifically treated. Elimination of physical, mental and emotional strain; administration of vasodilators like nitroglycerin; digitalis, quinidine, mecholyl for tachycardias; penicillin, streptomycin and sulfonamides for infections; intravenous saline solution, plasma and repeated blood transfusions, and administration of oxygen for shock or hemorrhage and finally digitalis, mercurial diuretics, acidifying drugs, a salt free diet for acute heart failure in patients suffering from coronary diseases will prevent the development of myocardial infarction incident to acute coronary insufficiency. These and many other measures are always ameliorative and may indeed be life saving (Master, A. M.; Dack, Simon; Grishman, Arthur; Field, L. E., and Horn, Henry: Acute Coronary Insufficiency: An Entity—Shock, Hemorrhage and Pulmonary Embolism as Factors in Its Production, *J. Mount Sinai Hosp.* **14**:8 [May-June] 1947).

The physician does not appreciate that episodes of acute coronary insufficiency are just as frequent as attacks of acute coronary occlusion. In a survey of office patients suffering from acute coronary diseases approximately half were instances of acute coronary insufficiency. My colleagues and I have gathered data from the hospital postmortem table and from figures published by medical examiners to show that the incidence is from 25 to 40 per cent of all fatal acute coronary diseases.

My purpose then in writing this letter is twofold: To draw a sharp distinction between acute coronary insufficiency and acute coronary occlusion and to emphasize my agreement with Dr. Dublin that physicians do not lead a "normal tempo of living." They work long hours, they are called out at night, they rush through their meals, they are subjected to mental stresses beyond those that prevail in other professions and occupations. They expose themselves to a variety of conditions which may act as precipitating factors in acute coronary insufficiency. How often has a physician, on a freezing February night, suffering from a cold himself, called on the telephone to see a patient, refused to make the visit? Not once in my experience.

Physician heal thyself!

Arthur M. Master, M.D., New York.

ALLERGIC PERITONITIS

To the Editor:—With reference to the case of "Allergic Peritonitis" reported in The Journal July 19, I do not think Sison and his co-workers are entirely justified in referring to it as "one form of allergy which has not been reported heretofore." In his monograph on "Food Allergy" in 1931 Rowe refers to a case characterized by acute abdominal crises found due to the ingestion of crab. At operation in one of the attacks there was found "diffuse congestion of intestinal coils with a considerable amount of gray sterile fluid." Fever, leukocytosis and the clinical signs of an acute condition of the abdomen had been present, but eosinophilia was apparently not noted.

There is the classic instance, described by Cooke, of recurrent abdominal crises in a woman of 24 which had begun in infancy. In each paroxysm there was fever as high as 104 F., leukocytosis to 28,000 and physical findings "as extensive as in general peritonitis." Removal of milk from the patient's diet effected a complete cure over a nine year follow-up period (*Bull. New York Acad. Med.* **9**:5, 1933). Althausen, Deamer and Kerr observed several instances of "The False Acute Abdomen," as presented in the *Annals of Surgery* (**106**:242 [Aug.] 1937 and described a case with signs of peritoneal irritation. Laparotomy was performed and urticaria of the peritoneum found, as proved by microscopic examination of the otherwise normal appendix. Wheat was found to be an important causative factor in that case.

In the *Annals of Internal Medicine* (**23**:1 [July] 1945) I reported 5 cases of "Benign Paroxysmal Peritonitis." Repeated crises of abdominal pain, fever and leukocytosis with signs of peritoneal irritation recurred over many years. Since then I have seen 7 more cases. In 2 there was hay fever and in a third asthma; in several there was a strong familial history of allergy; 1 patient had urticaria with his attacks.

Eosinophilia was absent in the acute episodes in all cases but was present, although in moderate degree, in the free interval in 2 instances. In none of the 5 cases in which it was possible to employ rigid trial diets was it possible to determine a definite food allergy. Skin tests were of little value. One woman patient gave a history that within three days after the birth of each of 3 children she had one of her typical acute febrile abdominal attacks, so that some form of puerperal infection was suspected. However, in none of the cases did ascites develop, as occurred in the case of Sison and his collaborators. That there was actual involvement of the peritoneum is indicated by the operative finding of a diffusely edematous peritoneum with a small amount of free fluid in 1 of the cases and definite peritoneal hyperemia in a second case. Incidentally, it is of interest that 5 male members of a family are affected by this disease.

The case reported by Sison and his colleagues adds supporting evidence to the concept that the allergic person is especially prone to acute, reversible peritoneal reactions. In many instances these simulate closely a surgical abdomen and all too often there is neither eosinophilia nor urticaria to warn the surgeon that he is dealing with a nonsurgical process.

Sheppard Siegal, M.D., New York.

STREPTOMYCIN AND EOSINOPHILIA

To the Editor:—I should like to comment on Dr. George T. Harrell's letter published in The Journal, August 2, page 1198.

In chronic infectious diseases, especially in tuberculosis, where progression and retrogression of lesions frequently occur simultaneously, the diagnostic and prognostic evaluation of the eosinophils is hardly possible. Even in far advanced and progressive cases their number is reduced to a much lesser extent and much less regularly than in acute suppurative conditions. Even if eosinophilia were a constant and reliable sign of healing in tuberculosis, the excessive increase in number to above 30 per cent—as seen in some cases undergoing streptomycin treatment—would be out of proportion and hardly explainable by Dr. Harrell's conception of liberation of firmly bound bacterial lipids. In other words, the often excessive number itself points to a toxic-allergic phenomenon rather than to an "eosinophilia of convalescence."

The fact that the eosinophilia rises to a peak and then recedes while therapy is still continued does not speak against its allergic origin. This is a known feature of both gold and neoarsphenamine treatments without any proved correlation between result of treatment and eosinophilia. On the other hand, it has been described that skin eruptions as to whose allergic nature there is but little doubt may also appear and disappear while streptomycin treatment is going on uninterruptedly. It remains to be seen whether streptomycin itself or some of its impurities are responsible for this allergic eosinophilia.

At this hospital in 8 pulmonary cases in which streptomycin was administered for four months, 2 showed excessive eosinophilia, 47 and 35 per cent respectively. Clinically and radiographically these 2 cases were neither the best nor the worst results in the series, the other 6 showing slight or no eosinophilia. The patient with the peak of 35 per cent eosinophils had a relapse within one month following completion of treatment while still having about 10 per cent eosinophils.

Even if the presence or absence of eosinophilia ever could be used as a means of estimating the efficacy of streptomycin treatment, eosinophilia would not have the same significance that reticulocytosis has in pernicious anemia. Reticulocytes not only are indicators but, being young erythrocytes, represent at the same time part of the result of the treatment, namely, newly formed, functionally adequate, vitally important elements of the blood.

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS
EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and the Examining Boards in Specialties were published in THE JOURNAL, Sept. 13, page 113.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: *Examination.* Montgomery, June 22-24, 1948. Sec., Dr. D. G. Gill, 519 Dexter Ave., Montgomery 4.

ARIZONA:* *Examination.* Phoenix, Oct. 7-8. Sec., Dr. J. H. Patterson, 826 Security Building, Phoenix.

ARKANSAS:* *Examination.* Texarkana, Nov. 6-7, 1947. Sec., L. J. Kosminsky, Texarkana. *Eclectic.* Little Rock, Nov. 6. Sec., Dr. Clarence H. Young, 1415 Main St., Little Rock.

CALIFORNIA: *Written.* Sacramento, Oct 20-23. *Oral.* Los Angeles, Nov. 8-9. Sec., Dr. Frederick N. Scatena, 1020 N. St., Sacramento 14.

COLORADO:* Denver, Oct. 8-11. *Final date for filing application is* Sept. 20. Sec., Dr. J. B. Davis, 831 Republic Bldg., Denver 2.

CONNECTICUT: *Examination.* Hartford, Nov 11-12. Sec., Dr. Creighton Barker, 258 Church St., New Haven.

DELAWARE: *Examination.* Dover, Jan. 13-15. *Endorsement.* Dover, Jan. 20. Sec., Dr. J. S. McDaniel, 229 S. State St., Dover.

DISTRICT OF COLUMBIA:* *Endorsement* Washington, Sept. 8. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6012 Municipal Bldg., Washington.

FLORIDA:* *Examination.* Jacksonville, Nov. 25-26. Sec., Dr. Harold D. Van Schaick, 6675 Windsor Lane, La Gorce Island, Miami.

GEORGIA: Atlanta, Oct. 14-16. Sec., Mr R. C. Coleman, 111 State Capitol, Atlanta 3.

HAWAII: *Examination.* Honolulu, Jan. 12-15, 1948. Sec., Dr. S. E. Doolittle, 881 S. Hotel St., Honolulu, T. H.

IDAHO: Boise, Jan. 13-15. Sec., Miss Estella S. Mulliner, 355 State Capitol Bldg., Boise.

ILLINOIS: Chicago, Oct. 14-16. Supt. of Registration, Dept. of Registration and Education, Mr. Philip M. Harman, Springfield.

INDIANA: *Examination.* Indianapolis, June 1948. Sec., Board of Medical Registration and Examination, Dr. Paul R. Tindall, K of P Bldg., Indianapolis.

KANSAS: Topeka, Dec. 3-4. Sec., Board of Medical Registration and Examination, Dr. J. F. Hassig, 905 N. 7th St., Kansas City.

KENTUCKY: *Examination.* Louisville, Sept 22-24. Sec., State Board of Health, Dr. P. E. Blackerby, 620 S. Third St., Louisville 2.

MAINE: Portland, Nov. 12-13. Sec., Dr. A. P. Leighton, 192 State Street, Portland.

MARYLAND: *Medical Examination.* Baltimore, Dec. 9-12. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore. *Homeopathic Examination.* Baltimore, Dec. 9-10. Sec., Dr. J. A. Evans, 612 W. 40th St., Baltimore.

MASSACHUSETTS: *Examination.* Boston, Nov. 18-21. Sec., Dr. H. Q. Gallupe, 413-E State House, Boston.

MISSOURI: *Examination.* St. Louis, Oct. 20-22. Exec. Sec., Mr. John A. Hailey, State Capitol Bldg., Jefferson City.

MISSISSIPPI: *Endorsement.* Jackson, Dec. 1947. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.

MONTANA: Helena, Oct. 6-8. Sec., Dr. O. G. Klein, First National Bank Bldg., Helena.

NEVADA: Carson City, Nov. 3. Sec., Dr. G. H. Ross, 215 N. Carson St., Carson City.

NEW HAMPSHIRE: Concord, Sept. 11-12. Sec., Board of Registration in Medicine, Dr. John S. Wheeler, 107 State House, Concord.

NEW JERSEY: *Examination.* Trenton, Oct. 21-22. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO:* Santa Fe, Oct. 13-14. Sec., Dr. LeGrand Ward, 141 E. Palace Ave., Santa Fe.

NEW YORK: *Examination.* Albany, Buffalo, New York and Syracuse, Oct. 6-9, 1947. Sec., Dr. Jacob L. Lochner, Jr., Education Bldg., Albany.

NORTH CAROLINA: *Endorsement.* Raleigh, Oct. 20. Act. Sec., Mrs. L. J. McNeill, 226 Hillsboro St., Raleigh.

NORTH DAKOTA: Grand Forks, Jan. 6-9. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

OKLAHOMA: *Endorsement.* Oklahoma City, Oct. 28-29. Sec., Dr. F. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

OREGON:* *Endorsement.* Portland, Oct. 17-18. Exec. Sec., Miss L. M. Conlee, 608 Failing Bldg., Portland.

PENNSYLVANIA: *Examination.* Harrisburg, Jan. 1948. Acting Sec., Board of Medical Education and Licensure, Mrs. M. G. Steiner, 351 Education Bldg., Harrisburg.

RHODE ISLAND:* *Examination.* Providence, Oct. 2-3. Chief, Division of Professional Regulation, 366 State Office Bldg., Providence.

SOUTH CAROLINA: Columbia, Nov. 10-12. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

SOUTH DAKOTA:* Pierre, Jan. 20. Sec., State Board of Health, Dr. Gilbert Cottam, Capitol Bldg., Pierre.

TEXAS: San Antonio, Nov. 12-14, 1947. Sec., Dr. T. J. Crowe, 918-20 Texas Bank Bldg., Dallas 2.

UTAH: *Reciprocity.* Oct. 8. *Examination.* Salt Lake City, June, 1948. Asst. Dir., Department of Registration, Miss Rena B. Loomis, 324 State Capitol Bldg., Salt Lake City.

VIRGINIA: Richmond, Dec. 4-6. Sec., Dr. K. D. Graves, 30½ Franklin Rd., Roanoke.

WEST VIRGINIA: *Examination.* Charleston, Oct. 2-4. Commissioner, Public Health Council, Dr. N. H. Dyer, State Capitol, Charleston.

WYOMING: *Examination.* Cheyenne, Oct. 6. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

ARIZONA: Sept. 16. Sec., Mr. Francis A. Roy, Science Hall, University of Arizona, Tucson.

ARKANSAS: *Examination.* Little Rock, Oct. 7. Sec., Mr. L. E. Gebauer, 701 Main St., Little Rock.

COLORADO: *Examination.* Denver, Sept. 17-18. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver.

CONNECTICUT: *Examination.* New Haven, Oct. 11. Exec. Asst., State Board of Healing Arts, Mr. W. G. *Reynolds, 250 Church St., New* Haven 10.

DISTRICT OF COLUMBIA: *Examination.* Washington, Oct. 20-21. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6012 E. Municipal Bldg., Washington.

FLORIDA: *Examination.* Gainesville, Nov. 1. Final date for filing application is Oct. 16. Sec., Dr. W. M. Emmell, University of Florida, Gainesville.

IOWA: Des Moines, Jan. 13, April 13, July 13, Oct. 12. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

MICHIGAN: *Examination.* Ann Arbor and Detroit, Oct. 10-11. Sec., Miss Eloise LeBeau, 101 N. Walnut St., Lansing.

MINNESOTA: *Examination.* Minneapolis, Oct. 7-8. Sec., Dr. Raymond N. Bieter, 105 M. Hall, University of Minnesota, Minneapolis.

NEBRASKA: *Examination.* Omaha, Oct. 7-8. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, State Department of Health, Room 1009, State Capitol Bldg., Lincoln 9.

OKLAHOMA: Spring 1948. Sec., Dr. Frank Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

TENNESSEE: *Examination.* Memphis, Sept. 18-19. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis.

WISCONSIN: *Examination* Madison, Sept. 27. Final date for filing application is Sept. 20. Sec., Mr. William H. Barber, Watson and Scott Sts., Ripon.

Medical Motion Pictures

FILM REVIEWS

Partial Gastrectomy for Gastric Ulcer. Prepared by R. P. Reynolds, M.D., and C. S. Kennedy, M.D. 16 mm., color, silent, 880 feet (one reel). Showing time thirty minutes. Produced in 1941 by Jam Handy Organization. Procurable from Grace Hospital, 1160 John R. Street, Detroit, Mich.

This film presents a technic of subtotal gastrectomy for gastric ulcer. The author uses a midline incision excising the umbilicus. The pylorus is transected about 2 inches proximal to the pyloric vein, the mucous membrane excised and the pyloric stump inverted with a double row of catgut. This type of procedure is indicated in a duodenal ulcer which interferes with closure of a duodenal stump, but there is no justification for it when the ulcer is located in the midportion of the lesser curvature of the stomach, as was demonstrated early in the film. The cautery was used to excise the stump of stomach adjacent to the crushing clamps, presumably to promote aseptic conditions, but later in the film the author handled the mucous membrane of the stomach and jejunum on numerous occasions with his fingers; although it is impossible to prevent a certain amount of contamination, it should be reduced to an absolute minimum.

Five Gm. of sulfanilamide was placed in the peritoneal cavity after completion of the operation. Interrupted steel wire sutures were used to approximate the fascia. Many surgeons would object to a loop of jejunum as long as 40 cm. proximal to the gastrojejunal anastomosis, even though it was placed anterior to the colon as illustrated.

The author appropriately showed application of towels to the skin edges, thereby emphasizing the importance of segregation of the skin from the operative field. The operative field was properly surrounded with gauze packs to prevent contamination of the rest of the abdominal cavity. The color photography is good.

Ventriculography. Prepared in 1943 by Harold C. Voris, M.D., Loyola University Medical School. 16 mm., color, silent, 800 feet (two reels). Showing time thirty-three minutes. Procurable on loan from Photographic Department, Loyola University Medical School, 706 South Wolcott Street, Chicago 12.

This picture illustrates the various methods of approach in injecting air into the ventricle. The film is entirely satisfactory and well documented and should be of interest especially for teaching purposes. There is no discussion on interpretation of the films obtained by the methods described. The photography is fair to good.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Failure to Examine Eyes Continuously During Tryparsamide Treatments for Syphilis.—The plaintiff sued for damages for total blindness alleged to have resulted from the malpractice of the defendant physician. From a judgment in favor of the defendant, the plaintiff appealed to the United States Court of Appeals for the District of Columbia.

Between November 1942 and February 1943 the plaintiff received seven injections of tryparsamide, an arsenical specific used in the treatment of cerebrospinal syphilis. Prior to these treatments he had received a complete neurologic examination, which included a thorough examination of the eyes. No reason was disclosed why the arsenical treatments should not be given. In February 1943 the plaintiff was referred to the defendant physician for fever therapy treatments with the recommendation that tryparsamide injections be continued. Defendant began administering fever treatments and continued the injections although he did not then make an independent examination of the plaintiff's eyes but relied solely on the abstract record received from Georgetown Hospital, in which the prior examination had been made. At no time thereafter did the defendant examine the plaintiff's eyes, except, as he said, to "look at them" when the patient was in the fever cabinet. After the ninth treatment plaintiff became ill and was removed to the Garfield Hospital, where he was found to be blind. The defendant admitted that he was neither experienced nor expert in the use and administration of tryparsamide and it is conceded that such treatment is extremely dangerous.

The plaintiff first contended that the trial court erred in refusing to instruct the jury that they might consider whether or not the failure of the defendant to give continuous eye examinations during the treatment was negligence. Expert witnesses for both the plaintiff and the defendant testified during the course of the trial. In response to a question as to whether, while a person is being treated for syphilis by fever cabinet therapy and tryparsamide, a careful and close examination or watch on the eyes should be kept, one physician answered "Yes." Another testified that the drug should be used cautiously. A third, who had been called as a witness for the defendant, testified:

> Q. Are there any special precautions to be taken in the use of tryparsamide? A. The eyes should be watched. The patient should be asked and occasionally the fundi should be examined, the eyegrounds should be examined and the fields examined.
>
> Q. And how should they be examined, Doctor? A. We have a machine in the clinic for that, and one of the interns takes the patient, and he has to point out certain points on a dial. That is a routine examination.
>
> Q. So your testimony would be that precautions should be taken and are necessary in the avoidance of possible ocular disturbances in the use of tryparsamide? A. Why certainly.

This evidence, said the court, was sufficient to warrant the submission to the jury, under a proper instruction, of the question as to whether or not the defendant's failure to exercise a continuous examination over the plaintiff's eyes constituted negligence. The trial court erred in refusing so to do.

The plaintiff insisted also that there was sufficient evidence to take the case to the jury on the question of proximate cause. The evidence showed that it was possible that the blindness might have been caused either by the syphilis itself or by the treatment, and that one of the first definite signs that tryparsamide is affecting the eyes is a sensation of light flashing. When this occurs an immediate examination should be made before continuing the use of the drug. The plaintiff testified that he told the nurse, whom the evidence shows defendant had placed in charge of the administration of the treatment, that he had experienced these light flashes. It is true that the nurse denied that he had made such a statement to her, but the jury was entitled to determine the truth as between the two witnesses, and if the jury accepted the plaintiff's statement in this respect, some ground would thereby have been established to justify the jury in reaching the conclusion that the proximate cause of plaintiff's blindness was the continued use of the drug. In this view, said the court, we cannot say that there was a total lack of evidence of proximate cause.

Accordingly the judgment in favor of the defendant was reversed and the cause was remanded for a new trial.—*Winstead v. Hildenbrand, 150 F. (2d) 25 (Dist. of Columbia, 1947).*

Use of Injunction to Restrain Violations of Basic Science Act.—This was an action to restrain the State Board of Chiropractic Examiners from issuing reciprocity certificates to applicants who failed to present a certificate from the Basic Science Examining Board. The defendant's demurrer was sustained, so the relator, prosecuting attorney, appealed to the Supreme Court of Arkansas.

The Basic Science Act fixes penalties for obtaining or attempting to obtain a license to practice any branch of the healing art from any board authorized to issue such license without first presenting to such board a valid basic science certificate. The act also provides (sec. 10808): "Any person who knowingly issues or participates in the issue of a license to practice the healing art or any branch thereof to any person who has not presented to the licensing board a valid certificate from the State Board of Examiners in the Basic Sciences . . . shall be fined not more than five hundred dollars or imprisoned not more than twelve months, or both in the discretion of the judge." The relator alleged that the State Board of Chiropractic Examiners had for many months been intentionally and illegally licensing applicants to practice chiropractic by reciprocity without requiring the applicants to present a certificate of ability in the Basic Sciences as required and that, unless enjoined, it would continue so to violate the terms of the Basic Science Act. The defendant demurred on the ground that the court was without authority to issue an injunction because there was an adequate remedy stated in the act for violations thereof.

The enforcement section of the Basic Science Act (sec. 10810) provides: "The State Board of Examiners of the Basic Sciences and of the various boards authorized to issue licenses to practice the healing art or a branch thereof shall investigate any supposed violation of this act and report to the proper county attorney all the cases that in the judgment of such board warrants prosecution. Every police officer, sheriff and peace officer shall investigate all supposed violations of this act and apprehend and arrest all violators thereof. It shall be the duty of the Attorney General and of the several county attorneys to prosecute violations of this act."

It is manifest, said the Supreme Court, that the Basic Science Act provides a plain and adequate remedy at law for the enforcement of its provisions without any necessity for applying to a court of equity to restrain a violation of its terms. Assuming, without deciding, that the State Board of Chiropractic Examiners is in error in licensing by reciprocity applicants from other states without first requiring presentation to it by such applicants of a certificate from the Basic Science Board, we think relator should have pursued the enforcement remedy provided by the Act. It is well settled, the court continued, that equity will not intervene by injunction to restrain acts that are merely criminal although "this does not preclude injunctive relief against the commission of criminal acts which cause irreparable injury to the complainant's property or pecuniary rights, even though the acts complained of are committed by public officers." Here, however, said the court, there is no allegation that the relator's property or pecuniary rights are invaded or threatened. This is a simple action to enjoin an alleged criminal violation of the Basic Science Act, for which violation the act itself prescribes serious penalties.

Being a suit to enjoin the defendant board from the alleged criminal violation of the Basic Science Act, we think, the court concluded, that the trial court was without jurisdiction and correctly sustained the demurrer to the complaint. The judgment in favor of the defendants was accordingly affirmed.—*State ex rel Robinson v. Crow, 199 S. W. (2d) 323 (Ark., 1947).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Cerebrospinal Fluid in Rheumatoid Arthritis.—According to Sundelin the symptomatology of rheumatoid arthritis includes a large number of neurologic symptoms which indicate that both the central and autonomic nervous systems are involved in this disease. The spinal fluid was examined in 141 patients with rheumatoid arthritis, of whom 58 exhibited a protein content that was pathologic in one way or another, 15 gave a pathologic colloidal gold reaction and 7 showed an increased spinal fluid cell count. Altogether 66 (46.8 per cent) were found to have spinal fluids which were pathologically altered. Although the presence or absence of such abnormalities could not be correlated with the presence or absence of neurologic manifestations, the changes noted may be an indication of nervous system involvement in rheumatoid arthritis.

Repeat Cesarean Section.—According to O'Connor the experience of individuals or of individual hospitals reveals that the mortality of repeat classic cesarean sections has been in the past 3.2 per cent. This risk probably can be reduced at the present time to about 1.5 per cent. A review of similar experiences with the low operation reveals a mortality of slightly over 1 per cent. In both procedures second cesareans bulk large, with a much smaller number of third cesareans and practically none beyond this. It is highly probable that the danger would have been greater than 3.2 per cent in classic and 1.2 per cent in low sections, were a larger number of fourth and fifth cesareans recorded. The remote dangers of rupture of the uterine scar and intestinal adhesions are great after the classic section and exist to a much less degree after the low section. A conservative type of section with sterilization removes the dangers of rupture of the scar and risk inherent in another future section but does not diminish the immediate mortality due to the procedure or the immediate and remote dangers from adhesions. Evidence is presented that elective cesarean hysterectomy is simple to perform, causes less blood loss, has a smoother convalescence and shows less morbidity than conservative repeat sections with or without tubal sterilization and in addition eliminates future dangers from a useless organ, the uterus. The procedure should be given much more consideration as an elective procedure at repeat sections and should often be performed on a patient over 40 years of age, in the presence of poor scars, when the uterus does not contract perfectly, in the presence of adhesions, after the third or more classic section and on patients who are subject to severe heart disease, kidney disease or tuberculosis.

Carcinoma of the Cervix.—*Given* presents a statistical analysis of 212 patients with cancer of the cervix uteri observed between 1933 and 1944. Sixty-five per cent of this number were classed as stage I and II and 35 per cent as stage III and IV. Of the 115 patients seen from 1933 through 1940, 49, or 42.5 per cent, survived for five years or more. The four, three, two and one year survival rates for the 97 patients seen from 1941 through 1944 are not appreciably different from the rates over the first period despite the fact that in 1940 radiation factors and technic were altered. There were about twice as many reactions in patients treated before 1940 as in those treated after 1940. This reduction in radiation complications is attributed to improved technic in radiation therapy.

Effect of Diphtheria on Pregnancy.—Robinson and his associates observed 4 patients with antepartum diphtheria. These women, with a fifth patient who was delivered in the Johns Hopkins Hospital in 1907, comprise the cases reviewed in this paper. There is no indication from these cases that adequately treated diphtheria increases the incidence of abortion or premature labor. No evidence was found in the literature nor was any obtained in these cases that might indicate the passage of diphtheria toxin across the placental barrier.

Frozen Foods as a Public Health Problem.—According to Fitzgerald frozen foods have been remarkably free from suspicion of being health hazards both as to enterotoxic food poisoning and as to infectious diseases. An acid forming streptococcus appears to be an active factor during spoilage, souring foods beyond edibility before enterotoxins can be elaborated. There is a possibility that pathogenic organisms may survive the freezing storage treatment and retain sufficient viability to cause infectious diseases. These could be a source of infection in frozen foods of the very best quality because the souring would not be present to warn the user. Frozen fruits and vegetables which may be served in raw salads could very well be the source of infections. These can be controlled only through careful sanitary procedures in factories. Laboratory methods of detecting the incidence of toxigenic or pathogenic strains of organisms are at present inadequate, and frozen foods may momentarily be implicated as health hazards. The industry has every reason to support thorough research designed to develop control technics.

Intravenous Ethyl Alcohol in Status Asthmaticus.—Brown says that a 5 per cent ethyl alcohol solution in physiologic 5 per cent glucose saline solution with or without epinephrine 1 : 1,000 (0.3-1.0 cc.), given intravenously at the rate of 80 to 100 drops per minute, effectively relieved severe bronchial asthma in 5 of 6 patients who did not respond to the usual medications given by the oral, subcutaneous and intravenous methods. Two of the patients responded similarly on two successive hospital admissions. No ill effects were observed.

Continuous Intravenous Aminophylline Therapy in Status Asthmaticus.—Goodall and Unger completely or partially eliminated status asthmaticus in 9 of 10 patients by a continuous intravenous administration of aminophylline. Relapse may or may not occur when the procedure is discontinued. Dosage consisted of up to 2 or even 3 Gm. of aminophylline dissolved in 2,000 cc. of 5 per cent dextrose in distilled water or of isotonic solution of sodium chloride alternating; the solution was given at the rate of 28 drops a minute. Large dosages of the drug should be used initially and very gradually reduced as the asthmatic symptoms subside. Aminophylline can be given in dosages up to 3 Gm. in twenty-four hours without undue danger to patients with severe bronchial asthma. Continuous intravenous aminophylline therapy is strongly recommended for most severe types of status asthmaticus, the types which have resisted all other kinds of therapy.

Study of Mitral Stenosis in Patients who Survived Age of 50. L. A. Baker and D. Musgrave.—p. [illegible].

Clinical Manifestations of Sickle Cell Anemia.—Grover lists the clinical manifestations of 48 cases of active sickle cell anemia. Patients with sicklemia without active symptoms have been disregarded. The previous concepts of the clinical features of this disease are confirmed. but particular attention is directed to the frequent occurrence of cardiac enlargement, presence of diastolic and systolic murmurs of the heart, prolongation of the PR interval, x-ray changes in the osseous system, rapid and obvious changes in the size of the liver and spleen, neuropsychiatric signs and symptoms, especially mental deficiency, and abdominal crises. Two unusual manifestations were the demonstration by esophagram of auricular enlargement in 2 cases and the relief of priapism by roentgen therapy.

Histamine in Peptic Ulcer.—Bernstein points out that procedures which have been recommended for the treatment of gastric ulcer are based on the assumption that acidity interferes with ulcer healing, and therefore a way must be found to depress or remove the gastric acidity permanently. He has gained the impression that, whereas the acid pepsin factor may be important, there appears to be no relationship between the maintenance of gastric acidity and the disappearance of either the symptoms or the anatomic defect or both. In contradiction to the implied dictum "neutralization of acid is necessary for the treatment of peptic ulcer" the author has used histamine, a potent acid stimulating, vasodilating agent. An average of twenty daily injections of 0.2 mg. of histamine phosphate were given to 75 ulcer patients. Except in the few instances in which tincture of belladonna also was used, no other medication was given. No untoward reactions were seen, except occasionally flushing and temporary headaches. In 50, or two thirds, of the patients complete relief from pain was obtained after the fourth injection, and over 80 per cent of the patients were relieved after less than ten injections. Five patients did not respond, 1 developed a fatal perforation and hemorrhage during treatment and another had a perforation soon after the histamine injections were begun. The deformities of duodenal and marginal ulcers showed great improvement under histamine treatment in some cases, and gastric ulcer was seen to disappear quickly. Twenty-six patients were protected against an anticipated recurrence by seasonal prophylactic injections.

Carcinoma of Breast.—Finney and his co-workers review 298 cases of cancer of the breast in which operation was performed during the fifteen year period from 1930 to 1945. All patients were treated surgically with 281 radical mastectomies and 17 simple mastectomies by four surgeons with an operative mortality of 1 per cent. Only 19 patients received either preoperative or postoperative radiation to the tumor site, while 7 patients of the premenopausal group were sterilized following radical mastectomy. Endocrine therapy has been used in only 3 cases, in all of which there were metastatic lesions. Of the 150 patients who did not die of cancer metastases, 70 per cent showed no metastatic lesions in their axillary nodes at the time of operation, while 30 per cent showed metastases. In this series the survival rates were 77 per cent after three years, 49 per cent after five years, 19 per cent after ten years and 4 per cent after fifteen years. Radical operation before metastasis has occurred in the axillary nodes gives the best prognosis.

Combined Surgery and Roentgen Treatment in Carcinoma of Breast.—Marshall and Hare say that radical surgical removal of breast carcinoma followed by intensive irradiation appears to improve statistical results in cancer of the breast and offers the best possibility for prolongation of life. In a series of 238 patients who received this type of treatment, 52 per cent were alive after five years or longer without evidence of recurrent tumor. The incidence of local recurrent tumors is materially reduced, there being only 8 per cent of such recurrences noted in this series. Radiation therapy given in large amounts by the divided dose method produced no serious complications. Failure results from spread of disease to distant areas prior to institution of treatment.

Radical Amputation and Bilateral Oophorectomy for Cancer of Breast in Premenopausal Patients.—Horsley reviews the recent literature on the influence of female hormone on breast cancer and the results obtained in breast cancer patients at St. Elizabeth's Hospital in Richmond, Va. Particular attention is given to the results obtained on 39 cancer of the breast patients in the premenopausal stage treated with radical amputation and oophorectomy. In this group 76.9 per cent lived without recurrence three and five years after operation. By comparison, patients who had undergone amputation but not oophorectomy had a five year cure rate of only 43.5 per cent. These patients were mostly of the postmenopausal period.

Tetraethyl Ammonium in Peripheral Vascular Disease.—Coller and his associates point out that the demonstration by Acheson and Moe that in animals the tetraethyl ammonium ion will block transmission of nerve impulses through autonomic ganglions led to investigation of the effects of this drug as a diagnostic and therapeutic agent. Administration of tetraethyl ammonium for the production of autonomic blockade proved of value in diminishing or relieving the severity of the pain of causalgia, posttraumatic painful states, herpes zoster, Buerger's disease and thrombophlebitis. The improvement following such therapy has been sustained in certain cases. The drug has proved to be a satisfactory implement for clinical investigation and therapy. Although tetraethyl ammonium injected intravenously in dosages of 500 mg. or less has not been accompanied with serious toxic effects, hypertensive patients, particularly those in whom a neurogenic component of the hypertension has been identified or suspected, should have great care exercised during administration. Precipitous drops in blood pressure have been encountered, associated with nausea, vomiting, sweating, pallor and temporary peripheral circulatory collapse. Nonhypertensive patients with an unduly labile sympathetic nervous system should also have the drug administered with caution. Elderly patients do not tolerate tetraethyl ammonium well. They should be given small doses, gradually working up to 500 mg. Some patients treated daily over a long period develop a mild myasthenia and lassitude, which disappears with cessation of administration of the drug. In small patients a 500 mg. intravenous injection may be followed by fasciculation of muscles. This is probably an evidence of overdosage. Large intramuscular doses in obese patients may produce the same effect, which may last for several hours. No ill effects have been noted from this pheuomenon.

Blood Picture in Pemphigus Vulgaris.—Grace reviews the results of blood studies made on 11 persons over periods ranging from twelve to one hundred and seventy-six days before death from pemphigus vulgaris. The effect was noted of clinical remission and relapse, impending death and increase of body temperature and administration of sulfanilamide. The proportion of eosinophils diminishes with deterioration of the general condition, and when a nonpruritic patient becomes sufficiently debilitated the eosinophil count may fall to zero. In the last two weeks of life the eosinophils do not exceed 6 per cent and are usually less; on the day of death they are few or absent. The terminal stages of pemphigus are associated with a relative and at times considerable monocytosis. This increase is probably a reflection of the role of the monocyte as a scavenger of particulate materials and bacteria. No relation exists between the degree of increase of monocytes and clinical remission or relapse, the presence of impending death or the administration of sulfanilamide. Monocytosis is therefore an even less sensitive index of the general condition in pemphigus vulgaris than is eosinophilia. The relative proportion of lymphocytes is unaffected by changes in the clinical picture. The red cell count is diminished. The blood picture is practically identical with that of a generalized infection. Leukocytosis, however, does not arise from an increase in the cells of the polymorphonuclear series; it is produced by an increase in the total number of each type of leukocyte present normally in the circulating blood. The absence of neutrophilia may be accounted for on the ground that the virus of pemphigus, in common with most viruses, is not a pyogenic agent.

Local Therapy with Penicillin Ointment Mixtures.—Goldman and his associates say that their experience with more than 400 cases shows that, when properly prepared and rationally employed, penicillin ointment mixtures are of value in dermatologic therapy. With penicillin ointments in their present state of development, certain factors must be considered in their preparation, storing, dispensing and application to insure maximum therapeutic effectiveness. Stability depends on the absence of water in the ointment, the use of a relatively stable penicillin salt such as calcium penicillin rather than sodium penicillin and the maintenance of sterility during preparation. The temperature of the mixture should not exceed 15 C. A concentration of 500 to 1,000 units of calcium penicillin per gram of ointment is preferable in most cases. The authors have used concentrations as high as 20,000 units per gram and produced no irritation and only rarely increase in sensitization. Among the conditions for which penicillin is regarded as definitely indicated the authors list impetigo, superficial impetiginized dermatitis, superficial pustular folliculitis, dermatophytosis with secondary pyogenic infection, superficial wounds, burns, biopsy areas, cyst cavities and the like. There are conditions for which penicillin is of possible benefit, such as infectious eczematoid dermatitis, pyodermas of the deeper type, ulcers, infectious exanthems, seborrheic dermatitis and sycosis barbae. Penicillin is of no value for deep infections in which the ointment cannot penetrate the infected area (carbunculosis or deep cellulitis), psoriasis, lupus erythematosus, pemphigus, dermatitis herpetiformis, "stasis" eczematoid dermatitis, acne vulgaris and herpes labialis. Eczematous contact reactions and other forms of reactions of the skin and mucous membrane are seen following topical penicillin therapy. The frequency and severity of these reactions will determine whether topical penicillin therapy in selected dermatoses is to be discarded in favor of equally effective nonsensitizing agents. If it is established that topical penicillin therapy also sensitizes a person so that adequate parenteral penicillin therapy cannot be given to that person in the future, topical penicillin therapy may have to be discarded.

Eosinophilic Granuloma of Bone with Cutaneous Manifestations.—Curtis and Cawley think that Letterer-Siwe disease, Hand-Schüller-Christian disease and eosinophilic granuloma of bone merit classification as closely allied manifestations of a basic disease varying chiefly in severity the exact nature of which is not known. Cutaneous lesions are of frequent occurrence with the first two but have not been described in conjunction with the last. The authors report observations on a girl aged 16 months who was referred to the dermatology clinic of the University of Michigan Hospital because of a cutaneous eruption. X-ray examination of the skull, chest, long bones and spine demonstrated a destructive lesion involving the axillary portion of the second rib on the right side, with an overlying swelling of the soft tissue in addition to a similar destructive lesion in the left ilium. A similar lesion subsequently developed in the right mastoid. Following roentgen therapy to the lesions of the bone and to the cutaneous eruption there was complete but gradual healing.

Symptomatology of Subdural Hematoma in Infants and Adults.—Govan and Walsh report observations on subdural hematoma in 37 infants and 54 adults. Certain anatomic observations are pointed out which may explain the differences in manifestations in the two age groups. They were impressed by the rarity of subdural hematoma in the age group from 2 to 20 years, the regularity with which hemorrhage occurred bilaterally in infants and unilaterally in adults, the regularity with which blood (or xanthochromia) was found in the spinal fluid of infants and its almost uniform absence in adults, and the frequent absence of a history of trauma in infants and the almost invariable history of trauma in the adults. Gross examination revealed an important anatomic difference between the supporting structures of the pial veins of the infant and those of the adult. In the infant the dura and the delicate arachnoid membrane are easily separated, and when the dura is retracted toward the midline several large pial veins are seen entering the longitudinal sinus. These vessels are short, nontortuous and without support. They appear to lie free in the subdural space. In sharp contrast, the dura and the arachnoid membrane of the adult are firmly bound together in the region of the longitudinal sinus. This attachment of the arachnoid to the dura is formed by masses of fibrous tissue forming the base of arachnoid villi (pacchionian granulations). It is plausible to think that in the adult, on account of the presence of these fibrous attachments, which must protect the pial veins entering the longitudinal sinus, a severer trauma would be required to rupture the vessels. The usual absence of a history of trauma in infants may perhaps be explained on the ground that only slight trauma might be required to rupture the veins in the infant on account of the freer mobility of the brain. The freer mobility of the brain might also explain why the subdural hematoma in the infant is almost invariably bilateral.

*Fibromyosis Uteri: Endometrial Type. J. H. Hill.—p. 527.

Fibromyosis Uteri: Endometrial Type.—After studying uterine fibromyosis of endometrial type as presented by a woman aged 46 and cases previously reported, Hill declares he does not believe that these cases should be called instances of endometriosis, as done by Goodall, because the stromal cell growth does not contain glands. He employs Frank's term "fibromyosis" to describe the growth observed in the present case, adding the phrase "endometrial type" to indicate the specific endometrial stroma type of fibrogenic growth which characterizes this condition. While the stromal cells are actively reticulogenic and form only collagen about the intrinsic blood vessels, the author thinks the "fibro-" is justified in view of the intimate connection known to exist between the argyrophilic reticulum and collagen. McDonald and his associates concluded that endometrial stroma sarcoma was to be viewed as a variety of fibrosarcoma, since the growth sometimes forms collagen. The "myosis" is necessary to indicate the associated hyperplasia of smooth muscle which accompanies the stromal cell masses. Since the stromal cell of the endometrium is unique, he feels that the qualifying phrase "endometrial type" is required to indicate the specific cell type comprising the fibrogenic tissue.

Bilateral Lobectomy for Bronchiectasis.—Bisgard and Swenson report 4 cases of bilateral bronchiectasis cured by bilateral lobectomy. In all cases the lower lobes of both lungs were removed, and in 1 case the middle lobe of the right lung also was excised. All but 1 of the patients are entirely free from symptoms. In this one there is some residual cough and sputum because the middle lobe of the right lung and the lingua of the upper lobe of the left lung are bronchiectatic, and the disease remains because it was not recognized prior to and at operation. Eight operations and 9 lobectomies were performed in the 4 cases—all by intralobar dissection and the individual ligation technic, with intratracheal cyclopropane anesthesia and frequent intratracheal aspirations. In 2 cases bronchopleural fistula with empyema developed, in each case after the first stage of operation, and in both cases the fistula closed spontaneously after drainage of the empyema. There were no deaths. In all cases not only good health but normal lives are being enjoyed, which the cough previously made impossible.

New Drugs in Malaria.—Packer says that during World War II, following the loss of the quinine supply of the Dutch East Indies, an extensive malaria research program was carried out. During the course of these studies over 14,000 drugs were tested. In the field type suppression, as in the suppression of the acute clinical attack, chloroquine and paludrine will undoubtedly supplant atabrine (quinacrine). These drugs have an advantage over atabrine in that they are effective when given once a week, whereas atabrine must be given almost daily. The great strides that have been made in the field of malaria chemotherapy in recent years under the pressure of the urgent wartime need for knowledge in this field will continue to be a valuable asset to the practicing physician. Physicians will be called on to treat relapsing vivax malaria acquired in the Southwest Pacific and in the Mediterranean areas for some time to come, in addition to indigenous cases. Mosquito control as the fundamental malaria control procedure is still needed.

Effect of Goitrogenic and Other Reducing Agents on Inactivated Thyrotropic Hormone.—Albert and his associates showed that treatment of a thyroid stimulating hormone extract with elementary iodine resulted in precipitation of most of the proteins of the extract. The brown iodinated precipitate was observed to have lost 95 to 100 per cent of its original thyrotropic activity. When the precipitate was triturated in an excess of acetone, 60 per cent of the iodine was removed, leaving a buff-colored protein residue containing the original thyrotropic potency. The conversion of inactivated hormonal material to activity has been accomplished in other ways. The authors demonstrate that the loss of thyrotropic activity occurring during exposure of a pituitary extract to iodine was restored in varying degree by treatment of the iodinated hormonal material with various goitrogenic and nongoitrogenic reducing compounds.

Augmentation of Thyrotropic Potency by Goitrogens.—Albert and his co-workers demonstrated that exposure of a pituitary extract to various goitrogenic compounds resulted in augmentation of its thyrotropic activity The augmenting effect was not abolished when the goitrogens were presumably removed from the hormonal material prior to bioassay.

Histoplasmosis in Man.—Lam and Price report that a man aged 45, of Portuguese extraction, entered the hospital complaining of "tightness" in his jaw. His condition gradually became worse. From the fifth hospital day the temperature rose slowly until the seventh day; it was 105 F. when he died with pulmonary edema. At necropsy diagnosis of histoplasmosis was made because the causative organism was discovered in the tissues. The disease was acquired in the Territory of Hawaii. This is believed to be the first case of histoplasmosis diagnosed in Hawaii.

Purpura Following Estrogen Therapy.—Five patients were observed by Watson and his associates in whom purpura followed administration of diethylstilbestrol or other estrogenic substances. Four of these were women being treated for menopausal symptoms or amenorrhea; one was an elderly man with carcinoma of the prostate. Four had received estrogen therapy, mainly diethylstilbestrol, for long periods, ranging from two and one-half to seven years. The fifth patient received estrogens parenterally, intermittently over a two month period. Evidence of hypersensitivity to diethylstilbestrol or estrone or both was manifested by each of the 3 patients available for skin testing, although absent in 25 controls.

Pernicious Anemia and Susceptibility to Gastric Neoplasms.—Kaplan and Rigler review statistical analyses which reveal that pernicious anemia and carcinoma of the stomach develop in the same individuals more often than would be expected on the basis of chance alone and must therefore be etiologically related. The evidence pertaining to the nature of this relationship is still inconclusive but suggests that the two diseases are probably linked indirectly through some common factor. Among the possible factors are hereditary or constitutional tendencies, achlorhydria, gastritis and liver therapy. In contrast to the paucity of gastric tumors discovered in nonselective mass surveys, serial gastric examination of persons with pernicious anemia has yielded a high incidence of benign and malignant epithelial tumors of the stomach. In serial x-ray examinations and gastroscopies of 211 patients with pernicious anemia described by Rigler and his associates two years ago 17, or 18 per cent, were found to have carcinoma of the stomach, and 15 (7.1 per cent) had benign polyps. Since then 48 new patients with pernicious anemia have been examined at the University of Minnesota, yielding 1 additional gastric cancer and 2 persons with benign polyps. Comparison of the reports from the Mayo Clinic over a period of twenty-five years reveals a distinct increase in the incidence of gastric cancer in patients with pernicious anemia. The greatly increased life expectancy of individuals with addisonian anemia since the introduction of liver therapy is generally offered as an explanation for this apparent increase in gastric cancer morbidity among them. The authors suggest that a search for other conditions etiologically related to or associated with gastric cancer is a necessary prerequisite to the establishment of practical, selective mass surveys for the early detection of neoplasms of the stomach.

Intravenous Treatment of Tetanus. E. S. Balles.—p. 232.

Peptic Ulcer Treated with Protein Hydrolysate.—Margaretten and Kamer were able to produce great improvement with a protein hydrolysate diet in 3 peptic ulcer patients in whom the Sippy regimen had failed. In 2 of the patients the ulcer remained radiologically visible at the end of treatment; in 1 the ulcer disappeared within a week. The hydrolysate is given in the form of a mixture of dextrimaltose, sugar and protein hydrolysate in pineapple juice. Vitamins are administered in high dosage. The amount of hydrolysate is 30 grains (2 Gm.) per pound of body weight (or 4.4 Gm. per kilogram). One feeding is given on arising and one on going to sleep, the others being distributed throughout the day to a total of eight to ten feedings. Proteins have acid-binding properties and represent logical medication for peptic ulcer.

Atypical Lymphocytes in Respiratory Diseases.—Waife points out that the presence of numerous atypical (monocytoid) lymphocytes in the blood is regarded as a characteristic and pathognomonic feature of infectious mononucleosis. Some reports have stressed the fact that these cells may be found in other clinical states, but this is not so generally known. During the winter of 1945-1946 the author observed 32 cases of various respiratory tract infections in which 125 blood smears proved the presence of the atypical lymphocytes. Heterophil agglutination tests were negative. This confirms other reports that the infectious mononucleosis blood picture is not specific for that disease and may be found in a variety of mild respiratory infections.

Clinical Evaluation of a New Sedative-Hypnotic (3,3-Diethyl-2,4-Dioxotetrahydropyridine) in Psychiatric Conditions. P. Polatin and W. A. Horwitz.

Shock Therapy During Pregnancy.—Kent employed various forms of shock therapy in 3 pregnant women. One manic depressive woman went through pregnancy uneventfully while receiving electric shock treatments in the sixth and seventh months of gestation. One paranoid schizophrenic woman miscarried at about four months while receiving her third course of combined electric convulsive therapy and ambulatory insulin. Another paranoid schizophrenic woman went through pregnancy to normal delivery while receiving ninety days of insulin (including eight genuine coma days) and twenty electric convulsive treatments in the fifth, sixth and seventh months of gestation. The author concludes from these observations that pregnancy should not necessarily be considered an indication to deprive a psychotic woman of needed shock therapy.

Glutamic Acid and Mental Functioning.—Zimmerman and his associates investigated the effect of l (+)-glutamic acid on mental functioning in children and adolescents. Of the 69 patients in this experiment 28 were children and adolescents with convulsive disorders. Eleven of this group of 28 were also mentally retarded. Thirty-three of the 69 patients were mentally retarded without convulsions. The most striking changes appeared in the seriously retarded group, in which statistically significant differences were obtained between test and retest intelligence quotients. Greater improvement occurred on tests requiring abstract thought than on those involving motor skill. In many cases a greater degree of emotional stability resulted.

*Incidence of Poliomyelitis in 1946. C. C. Dauer.—p. 901.
*Fly Abatement Studies in Urban Poliomyelitis Epidemics During 1945. J. L. Melnick.—p. 910.

Incidence of Poliomyelitis in 1946.—Dauer says that during 1946 more cases of poliomyelitis were reported in the United States than for any prior year except 1916 The high incidence of poliomyelitis in 1946 involved chiefly the north central part of the country. There has been a mounting increase in ratio of cases to deaths in recent years, which is probably due to more complete reporting and inclusion of a greater proportion of nonparalytic cases. Poliomyelitis was also more prevalent in other parts of the Western Hemisphere in 1946. Epidemics appear to occur more frequently in tropical areas than is commonly stated. Accumulations of epidemiologic data in recent years appear to have strengthened the hypothesis that poliomyelitis is spread principally by person to person contact.

Fly Abatement Studies in Epidemics During 1945.—According to Melnick and his associates DDT was applied in two poliomyelitis epidemic areas, each with an area of about 4 square miles and inhabited respectively by some 67,000 and 27,000 people. A temporary reduction in flies was achieved in both areas. In the circumstances, which were not ideal, there was no effect on the poliomyelitis epidemic in either area. The authors think that the inconclusive results obtained in this work cannot be accepted as a final answer to the question.

Gaining Cooperation from Alcoholic Patient.—Tiebout says that many physicians think that little can be done for an alcoholic addict unless he is willing to cooperate—and that usually he is not cooperative. This statement fails to take into account the fact that gaining the patient's cooperation should be regarded as the first part of a therapeutic process. Every sufferer from the disease of alcoholism passes through a long period when he is completely resistant to the idea that he is sick and should have help. No patient will cooperate with treatment unless he is conscious of the need for help. As a preliminary to feeling the need for help the patient must undergo certain experiences which produce that consciousness. In the alcoholic patient these experiences may be divided into two stages: (*a*) the stage when he is learning that alcohol is a problem to be tackled and (*b*) the stage when he is discovering that his own methods of tackling the problem are doomed to failure. At the outset of any contact with a person in need of help, the one who is in a position to help has the initial responsibility of inducing a willingness and a capacity to accept that help. The author discusses the steps by which this capacity is attained. Every person must take these steps before he can accept his role as patient. All that any therapist can do initially is to guide him in taking them, and this is an essential part of the therapeutic function.

Erosive Bone Lesions and Soft Tissue Ossifications Associated with Spinal Cord Injuries.—Heilbrun and Kuhn describe erosive bone lesions and soft tissue ossifications observed in a survey of 99 cases of paraplegia. Although they frequently occur in the same person, they are not related etiologically. The erosive lesions develop where soft tissue becomes devitalized over bony prominences such as the trochanters. There is a subacute and chronic infection of the tissue overlying the bone, with extension to the superficial layers of bone. This leads to resorption of the cortex and the underlying trabeculae. The bone marrow is replaced by fibrovascular tissue which accompanies the low grade inflammatory process. The cause of the development of the soft tissue ossifications is not understood. Although soft tissue trauma may assume an important role, the neurogenic influence cannot be disregarded.

Pulmonary Pseudocysts Associated with Pneumonia.—Flax and his associates say that true congenital lung cysts are rare and suggest that many cases that suggested congenital pulmonary cysts by x-ray were probably examples of acquired emphysematous cavities. These may develop during an infection of the respiratory tract in which a portion of the bronchial tree becomes occluded by inflammatory exudate and mucosal swelling with the formation of a check valve obstruction. The regional alveoli then become distended and may rupture. With the coalescence of a group of ruptured alveoli a large emphysematous cavity is formed; in infected areas inflammatory exudate may seep into the cavity and produce air-fluid levels. The authors present the histories of 2 infants with severe pneumonia in whom the x-ray revealed large lung cavitations. The differential diagnosis included the possibility of lung cyst, lung abscess, diaphragmatic hernia and pulmonary tuberculosis with cavitation. On penicillin therapy both children responded with gradual clinical improvement. Serial x-ray studies demonstrated the disappearance of the cavities with the subsiding infection and removal of the bronchial obstruction.

Falsely Negative and Positive Reactions in Syphilis.—Kolmer says that no test can be sufficiently sensitive for the detection of all cases of syphilis. All tests now employed can be made more sensitive by technical modifications but only at the expense of falsely positive reactions. It is far better to miss the serum diagnosis of an occasional case of chronic syphilis than to incur the risks of falsely positive reactions in nonsyphilitic individuals. The clinician should never permit negative reactions to override his clinical judgment. Positive serologic reactions should never be ignored simply because they are clinically unexpected, since they may be, and frequently are, the only evidence of syphilis. Unexpected positive reactions should always be checked along with thorough clinical examinations, before the patient is informed or treatment instituted. While a large percentage of falsely positive reactions are due to errors in technic, all serologic tests are capable of yielding biologic falsely positive reactions regardless of every precaution against technical errors. In all tests, however, they are much less likely to occur with spinal fluids than with serums. Falsely positive reactions should be suspected when (*a*) the reactions are consistently weak or doubtful with occasional stronger reactions, (*b*) when discordant results are observed in different laboratories and (*c*) when negative complement fixation and positive flocculation reactions are observed. Under these conditions judgment and treatment should be withheld, but the tests should be repeated at intervals over a period of at least three to six months.

Dust Hazard in Tremolite Talc Mining.—Greenburg reports a study of the tremolite talc mining and milling industry in northern New York State. In a group of 221 tremolite talc miners and millers, advanced fibrosis was found in 32 men. All patients were men who had been working with tremolite talc for ten years or longer. Among this group of 107 men the incidence was 29.9 per cent. The fibrosis was of a fine diffuse type with the x-ray appearance of granulation or nodulation on a hazy background. It tended to be disabling in character and was frequently accompanied with dyspnea, cough and fatigue. There was also some evidence that this fibrosis was characterized by an increased susceptibility to tuberculosis. In addition to fibrosis, deposits of unidentified opaque material in the periphery of the lungs, so-called talc plaques, were observed in 6.3 per cent of all tremolite talc workers. These deposits could not be identified with any particular signs or symptoms. The author concludes that tremolite talc is a silicate dust capable, like asbestos, of causing a disabling pneumonoconiosis.

Geriatrics in Industrial Medicine.—Kuh points out that out of the need for manpower the war brought about a favorable change in attitude toward the employment of older persons in industry. It is important to continue their employment, for otherwise we shall saddle on the diminishing fraction of younger persons an increasing burden to support the aged either directly or indirectly through taxation. Age brings with it compensations that tend to maintain the value of the aged person to the employer. Older persons have fewer accidents and, while speed of reactions may decline with age, there is increased skill and better judgment as the result of longer training and experience.

Primary Tuberculous Infection in Childhood.—Thompson reports results of tuberculin tests on 1,476 children below the age of 14 who attended a chest clinic in London. Of these, 1,050 came primarily without symptoms, as contacts of known cases of tuberculosis. The remaining 426 were referred on account of specific symptoms. The 1,050 were designated "contacts," the 426 "noncontacts." Seven of the children died. None of the 426 noncontacts died. Of the 41 patients whose condition was diagnosed outside the clinic as tuberculosis, 1 died—a child with generalized tuberculosis already moribund when notified. The six remaining deaths took place among the 1,050 contacts. All 6 children were in contact with a sputum positive adult at or near the time of being found tuberculin positive. The rapidity with which death ensued is in keeping with the observation of Wallgren that fatal generalization from a primary complex occurs almost invariably at about twelve weeks from the development of tuberculin sensitivity. Observations on the children tested and on other tuberculous patients in the area under consideration indicate that the majority of the deaths from tuberculosis in children occurred suddenly, in the absence of a history of contact or of prolonged illness. It therefore does not appear that treatment can be expected to influence the outcome in children with primary tuberculous infection or that the detection of a higher proportion of such cases by intensified diagnosis is likely to diminish the general mortality. We cannot say whether any given child will or will not undergo a rapid and fatal generalization of the disease, nor probably have we at present power to influence the issue. We can predict with some confidence a more or less complete recovery if the first three months are survived. Those who will develop phthisis after adolescence are more likely to do so by reason of continued or resumed contact. The cleaning out of infectious tuberculosis from each household, therefore, becomes a paramount object. It would seem that the mortality from tuberculosis in childhood can be substantially reduced only by discovering and eliminating infectious tuberculosis in adults.

Purpura Necrotica and the Shwartzman Phenomenon.—Sheldon describes 3 cases of an illness which seems to attack children chiefly, if not exclusively. It begins with features typical of an attack of allergic purpura; the purpuric lesions are associated with necrosis of the tissues, and healing is accompanied with separation of the resulting sloughs. These vary in severity from necrosis of the superficial layers of the skin to lesions penetrating deep into the underlying muscles, resulting in severe and permanent scarring. It is suggested that the disease may be connected with the Shwartzman phenomenon and that in the early stages it may be characterized by short, critical phases during which the operation of slight but continued pressure may determine areas subsequently to be the site of deep necrosis. The scars have a distinctly artificial appearance, especially the straight sides joined by a right angle. It is common to see linear marks on the buttocks of patients caused by pressure from the crumplings and folds of their pajamas, and such lines at times mark out a triangle. Such an explanation involves, however, the further assumption that during the active period of the disease there is a critical phase within which the sensitizing process reaches a maximum, so that quite slight but continued pressure can mark out areas on the skin subsequently to be the site of deep necrosis.

Surgical Emphysema Due to Compressed Air.—Desmond thinks that the hazards associated with the careless use of compressed air are recognized but that the occurrence of tissue emphysema in the presence of even the smallest wounds has not been sufficiently brought to notice. He reports the experience of a metal miller aged 16 whose hand had been hurt by a small piece of metal shaving ("swarf"), which had punctured the ulnar side of the palm. The boy removed it, and the wound bled a little. He then, in an attempt to remove the remainder of the "swarf," directed the nozzle of an air compressor pump on to his hand, which instantaneously became ballooned and painful. An x-ray showed air in the soft tissues of the ulnar side of the hand and of the webs between the fingers. He was treated with local heat, sling immobilization and a prophylactic course of sulfadiazine. Next day the hand remained swollen but was less painful. Sulfadiazine and immobilization were continued. The following day the swelling had completely subsided; there was full function and no pain. A further x-ray examination showed a normal soft tissue shadow, and he returned to work six days after the accident. Workmen should be warned; not one workman at the small metal milling factory at which this incident occurred was aware of these dangers.

Digital Foreign Bodies in Spot Welders.—Reynard and Smith observed an industrial injury to the hand and fingers sustained by employees engaged in spot welding. The first of the 12 injuries described in this report was sustained by a woman aged 18 who while spot welding small steel brackets on Nov. 13, 1945 received a jet of sparks from the welding machine into the tip of her right forefinger. She felt a stabbing pain and rapidly the finger became white at the tip, was painful and began to swell. On November 20 she reported the injury at the works hospital. Kaolin poultices were applied daily for a week. At the end of that time a small metallic foreign body was picked out with an eye spud, and temporarily the condition was settled. On Jan. 1, 1946 the finger became painful again; another piece of metal was removed and a small pinhead abscess evacuated. By February 25 she complained of a pricking sensation in the finger when handling small objects, and tenderness to the slight touch. Her disability had necessitated a change of job to one in which fine finger movements were not essential. On March 11 a lateral incision was made, extending into the cornified entry wound at the finger-tip, and a minute superficial cavity containing necrotic material was opened up. Deep and proximal to this cavity the metallic foreign bodies were located and as many as possible extracted with the point of the knife. The wound healed by first intention, and when seen again recently the patient had no complaint. She had returned to her old job of spot welding. This and other cases described indicate that the lesion consists of a superficial burn, minute entrance wounds and underlying foreign bodies. The most satisfactory preventive device to date are cotton gloves coated with "Neoprene" and asbestos fabric finger stalls worn under the usual cotton gloves.

Clinical Trial of Di-Insulin.—Slessor and Nicol say that Hey of Denmark reported success with an insulin mixture, di-insulin, which exerts a rapid and prolonged action. This preparation consists of equal parts of soluble insulin and of a new derivative, phenyl-ureido-insulin (iso-insulin), which Hallas-Møller developed in 1944. In contrast to the protamine insulins, iso-insulin has the desirable property of being miscible with soluble insulin without altering the proportions of the two components. Its effect lasts sixteen to twenty-four hours after injection. The mixture di-insulin is a clear solution containing 40 units per cubic centimeter. After testing di-insulin on 5 healthy men, the authors used it on 12 diabetic patients. They found that the protracted effect of the iso-insulin component was demonstrable in normal persons and in diabetic patients requiring less than 50 units of insulin. In the latter a single injection of di-insulin controlled the blood sugar throughout the twenty-four hours; but in those requiring 50 units or more one injection of di-insulin was unsatisfactory, producing hypoglycemia three to eight hours after injection and not controlling the blood sugar in the late evenings and during the night. The soluble insulin content in the di-insulin mixture is thought to be too high.

Vi Bacteriophage in Typing of Typhoid Bacilli.—According to Craigie and Felix the phage typing method reveals strain differences which cannot be demonstrated by any serologic method. A carrier may be absolved from responsibility for a given outbreak if he is excreting a strain of Salmonella typhi which differs in Vi phage typing from those isolated from the cases. Any typing scheme recommended at present must be designed to accommodate new types that may be found later in different parts of the world. Provision will have to be made by an authoritative international body, so that reference standards, both cultures of Vi type strains of S. typhi and standard typing phage preparations, should be available to all using the method. A scheme which is to be used as an epidemiologic guide must be based primarily on epidemiologic evidence. The epidemiologic information which has been accumulated in various countries to date has been carefully considered before proposing the scheme presented in this paper. All the phage preparations used for the identification of the types and subtypes listed in the proposed scheme have been derived from one strain of specific typhoid Vi bacteriophage: the Vi phage II (strain 6) described by Craigie and Yen in 1937 and 1938. Until extensive comparative investigations have been made, the routine typing of strains of S. typhi should be carried out exclusively with the preparations of Vi phage II giving the reactions specified in the scheme. The authors discuss types and subtypes that merit special comment and describe the material and methods required for typing with Vi bacteriophage.

Iodine Treatment in Monilial Infections.—Weekes used liquor iodi mitis locally twice a week in the treatment of 50 patients with monilial infection of the vagina. It was found to be the quickest and most successful treatment so far used at the clinic and is now being used there almost exclusively. Thirty-eight of the 50 patients treated were cured; all pruritus subsided and no growth of Monilia was obtained on attempted culture for at least one month after the final treatment. The cured patients have remained free from signs and symptoms for from eight to three months. The number of paintings necessary to effect cure ranged from one to nine, the majority of patients requiring three to four paintings, with an interval of three days between paintings. In 6 of the 12 patients not cured by iodine the monilial infection was complicated by diabetes mellitus, chronic salpingitis, vulval warts or pregnancy. Only 4 of the patients not responding to iodine had simple monilial vaginitis.

Nutritional Liver Disease in West Indian Infants.—Waterlow says that a disease occurs among babies in the West Indies whose main features are edema, gross muscular wasting and fatty infiltration of the liver. The onset is usually within three months of weaning. The edema is of the hypoproteinemic type, without albuminuria. The mortality of the disease is high. Analysis of the liver in fatal cases shows a fat content of up to 50 per cent of the fresh weight. Hepatic functional impairment may be demonstrated during life by the sulfobromophthalein test. This syndrome resembles closely the disease known in Africa as kwashiorkor, or infantile pellagra. In the African cases there are typically severe lesions of the skin and mucocutaneous junctions and depigmentation of the hair. In the West Indian babies lesions of the skin, hair and mucosa were seldom severe and were sometimes absent. It is generally agreed that the underlying cause is a dietary deficiency of some kind. In the West Indies it was found that a striking improvement occurred with no other treatment than an increased intake of milk. On an intake of 7 or 8 ounces daily the condition remained more or less stationary; when the intake was increased to 30 ounces there was a rapid loss of edema, a rise in serum protein concentration and in dye clearance, and a more gradual decrease in the size of the liver. The history and the response to treatment suggest that the underlying deficiency in this fatty liver disease is either of protein or of some member of the vitamin B_2 complex. Enlargement of the liver without enlargement of the spleen is an indication for a supply of extra milk.

*Influence of Treatment with Penicillin on Development of Acute Osteomyelitis Caused by Staphylococcus Aureus. J. Leveuf and G. Laurence. —p. 78.

Effect of Local Application of Penicillin on Tissues and Treatment of Wounds. A. Ritter and A. Pletscher. —p. 106.

Penicillin in Acute Osteomyelitis.—Leveuf and Laurence say that at the surgical section of the children's clinic of the Paris faculty 78 children with acute osteomyelitis were treated with penicillin. They describe the treatment employed at their clinic before the introduction of penicillin and cite the results obtained with it. When penicillin was introduced, the dosage was at first 100,000 units daily, but later up to 500,000 units was given daily by intramuscular injection. Otherwise the treatment was practically the same as it had been before the introduction of penicillin. One fatality occurred among the 78 cases. The authors think that most of the 7 cases, in which the diagnosis had been based only on clinical evidence and which progressed without suppuration and without the appearance of x-ray signs, were probably diagnosed erroneously. Forms that did show x-ray signs but did not progress to suppuration were somewhat more frequent with penicillin therapy (21 of 78) than without it. The usual course with abscess formation and sequestration was observed in 45 of the 78 cases. Introduction of penicillin into the medullary cavity was tried in 4 cases but then was abandoned. The authors conclude that analysis of the influence of early treatment of acute osteomyelitis on its evolution, the temperature curve, the blood cultures, the virulence of the microbes, the length of suppuration and sequestrum formation has not demonstrated that the effect of penicillin is spectacular. They point out that reports of the replacement of emergency surgery, such as trepanation, with penicillin are inconclusive because they merely demonstrate the evils of emergency operation.

Tuberculosis of Eye: Jensen's Retinitis. G. Renard.—p. 376.

*Grave Febrile Anemia in Association with Acute Leukosis Treated with Penicillin and Repeated Transfusions; Apparent Recovery for Twenty Months. J. Decourt, R. André and J. Guillemin.—p. 378.

Progressive Scleroderma.—Harvier and Bonduelle report the occurrence of the Thibierze-Weissenbach syndrome in a woman aged 29 with progressive scleroderma of fifteen years' duration. Considerable calcification of the liver and spleen was demonstrated by x-ray, revealing precisely the outlines of these organs. Interhepatosplenic trails of shadows seemed to belong to the branches of the celiac trunk. The contour of the spleen was reduced after an injection of epinephrine. Functional liver tests gave normal results. It is suggested that the calcium is deposited in the capsule of the organs involved and that it is of no importance for the prognosis.

Ligation of Inferior Vena Cava.—Léger and Oudot ligated the inferior vena cava in 3 women between the ages of 29 and 44 and in 1 man aged 50 with repeated pulmonary embolism. The embolic process was checked immediately by the operation. The inferior vena cava was ligated also in 2 women with phlebitis, one of whom was pregnant near term. The occurrence of embolism with pulmonary infarction was prevented, and recovery resulted in both cases. Intervention consisted of ligation in 3 of the cases, while a section was made between two ligatures of the trunk of the inferior vena cava in 3 other cases. The vein contained a clot in 2 cases. The vein appeared to be free in the 4 other cases. The difficulty of appreciating the anatomic condition of the vein by simple inspection or palpation is emphasized in 3 of these cases in which ligation was employed without section. Additional observations are required for answering the question whether ligation of the inferior vena cava should be carried out immediately after the first embolism whose recurrence is threatened or whether ligation should be employed in the presence of manifest phlebitis.

Penicillin in Grave Febrile Anemia.—Decourt and his co-workers report the occurrence of grave anemia with leukopenia, temperature up to 104 F. and prostration in a youth aged 19. An acute leukosis was revealed on blood examination. The bone marrow was almost completely invaded by cells of the same type. Treatment consisted in daily blood transfusions for two months, with a total amount of 10 liters of blood and administration of 100,000 units of penicillin for twelve days. Blood cultures which preceded the administration of penicillin were negative. Recovery resulted after a grave course of two months' duration with prolonged mental disturbances. The blood count and the bone marrow remained normal for twenty months. Although the diagnosis of leukosis was confirmed by several hematologists, it still appears doubtful. The possibility of an exceptionally prolonged remission is to be considered.

Cerebrospinal Fluid Changes in Wassermann Positive Bronchopneumonia.—Hegglin observed in 1940 among mountain troops a form of pneumonia in which the serologic reactions for syphilis were positive. Later investigations suggested that this so-called Wassermann positive pneumonia was an infection of the air passages by a specific virus. The virus genesis is indicated among other factors by the positive cold agglutination. This also indicates a relationship to infectious mononucleosis, which is also often accompanied not only by cold agglutinations but also by syphilitic reactions. The author studied the cerebrospinal fluid in 9 cases of bronchopneumonia in which the blood Wassermann reaction had been positive. A positive result was obtained in 2. Both demonstrate that in pseudosyphilitic bronchopneumonia cerebrospinal fluid changes may occur which may simulate a syphilitic cerebrospinal disorder.

*Beginning of Pulmonary Tuberculosis in Adults. G. Sayago and M. Gomez Casco.—p. 57.

Pulmonary Tuberculosis.—The lack of early symptoms in adults suggests that an early diagnosis requires a systematic and repeated radiologic survey of people and the importance of tuberculin controls principally of ambulant persons, among whom the possibilities of primary infection are greater. The influence of contagion among people at the beginning of adult reinfection is demonstrated by epidemiologic, anatomic and clinical research. The first changes in the roentgenograms in the initial forms of adults consist of the appearance of infiltrative focal processes, which aspect varies from that of cloud infiltrates to that of the typical shadows of early infiltrates. Hematogenic spread as the initial form of tuberculosis in the adult is rare. The danger of contagion in most initial forms exists in 35 per cent of cases, since bacteriologic investigations of gastric contents are positive in that proportion.

Cancer Biotherapy.—Klyueva points out that the action of the South American trypanosome Schizotrypanum cruzi was investigated in 1938 by Roskin. In a normal animal trypanosomes multiply in the heart, spleen, liver, bone marrow and lymph nodes. In an animal with a malignant growth the trypanosomes are absent from these organs and are concentrated in the neoplasm. Schizotrypanum cruzi destroys the malignant cell. First there is a degeneration of the nucleus, and then the cell disintegrates. A similar effect is produced also by killed trypanosomes. In 1939 Roskin and Klyueva prepared an endotoxin of trypanosomes killed by heating. The endotoxin had the same effect on the malignant cell as the live culture. Roskin in 1941 injected a patient with KR prepared from trypanosomes. Small doses of the preparation were harmless but caused the destruction of the new growth. These investigations, interrupted by the war, were continued in 1944. Subcutaneous, intramuscular or intratumor injections of the cancerolytic substance KR were given to patients with malignant growths and caused disintegration of the tumor. In 5 of 10 patients with laryngeal cancer the tumor disintegrated. A favorable cancerolytic effect was observed also in 3 patients with advanced cancer of the cervix, in 3 out of 5 with inoperable cancer of the breast and in 1 patient with incurable carcinoma of the lip.

Action of Bromine Salts on the Thyroid.—Emelyanova says that the department of general biology of the First Moscow Medical Institute has investigated the relationship of the thyroid gland to halogen compounds. The author is concerned chiefly with potassium bromide, the effect of which was studied in various species of animals. The thyroids of animals treated with potassium bromide showed increased activity. Transplanted thyroids of mice treated with potassium bromide induced accelerated metamorphosis of tadpoles. The experiments on tadpoles confirmed the conclusion that under the influence of potassium bromide the secretory activity of the thyroid gland is increased, as a result of which accumulation of the colloid containing hormonal principles occurs in the follicles of the gland.

Intestinal Necrosis: Pathologic Aspects.—Jeckeln of the Pathologic Institute of Lübeck says that during the summer of 1946 a new disease was observed which was first identified in the course of necropsies. A peculiar necrotic process attacks the intestinal mucosa. The observations were made on 35 postmortem and 7 surgical specimens. Three stages are differentiated in the disease process, but death may occur in any stage. The fully developed third stage is characterized by (1) necrosis of the mucosa with a sloughing tendency, (2) penetration of the necrosis into the submucosa and the muscularis and (3) hemorrhagic edema of submucosa, muscularis and subserosa. Microscopic examination reveals thrombosis in the vessels of the submucosa, particularly where the necrosis penetrates the deeper layers. Probably the most frequent sequels of the process are hemorrhages, which may occur during the early stage. Perforation, although not to be expected during the early process, may appear at any time later and it may not be limited to one break, as many perforations may develop. The upper portion of the small intestine is usually the site of the severest involvement, but the lower part of the small intestine and even the colon may become involved. The stomach usually remains free. In mild cases healing takes place with a smooth scar.

Clinical Aspects of Intestinal Necrosis.—Ruppert observes that the onset is usually acute, with severe colicky pains usually in the upper part of the abdomen. The tongue is dry and coated; the patient refuses food. The abdominal pain is usually most severe on the left side, with increased rigidity and hyperalgesia of the skin. Meteorism exists and constipation is followed by diarrhea, with blood in the feces. *The sedimentation rate of the erythrocytes is increased; there* are leukocytosis and deviation to the left and toxic granulation. Frequently there is cutis marmorata as an indication of capillary toxicosis. Early complications include peritonitis, paralytic ileus, diplegia or tetraplegia and Landry's paralysis as the result of capillary hemorrhages in brain and spinal cord (capillary toxicosis). Late complications may take the form of adhesive peritonitis, perforation peritonitis, adhesion ileus or obstruction ileus. The etiology is still unknown, but a relationship to dysentery, cholera or arsenic poisoning can be excluded. The administration of mild laxatives, compensation for the loss of water, transfusion and support of the peripheral circulation are the usual therapeutic measures. Occasionally surgery may be necessary. The prognosis is usually doubtful, since the mortality averages about 40 per cent.

*Plaut-Vincent's Disease. H. Fermin.—p. 1223.
Diabetes and Pregnancy. B. S. ten Berge and F. J. J. van Assen. —p. 1229.
*Phrenicoclasia and Pneumoperitoneum in Treatment of Pulmonary Tuberculosis. P. Zuidema.—p. 1233.
Modern Hearing Devices. W. J. Pqthoven.—p. 1242.

Plaut-Vincent's Disease.—Fermin shows that Plaut-Vincent's angina or stomatitis may assume different forms and that the supposed causal organisms, Vincent's spirochete and Bacillus fusiformis, occur in other infections and even in normal mouths. The noninfectious gingivitis and infectious trench mouth are assumed to have a different epidemiology. Stress is *placed on the prophylactic* and therapeutic *importance of* systematic oral hygiene. Reviewing his experience as a military physician with Plaut-Vincent's disease, the author emphasizes the favorable therapeutic results he obtained with the use of lozenges containing 300,000 units of sodium penicillin in the treatment of patients with Plaut-Vincent's disease. The lozenges are left in the mouth; one usually dissolves in the course of an hour, so that about ten are required for one day. Cure was usually obtained in the cases of this disease reported by Fermin in about four days.

Phrenicoclasia and Pneumoperitoneum in Pulmonary Tuberculosis.—It was Maurer who suggested that the therapeutic effect of paralysis of the diaphragm produced by phrenic exeresis be systematically supported by pneumoperitoneum. Zuidema describes the technic of this combined treatment and presents cases to illustrate the favorable effect of this treatment in patients with pulmonary tuberculosis.

Book Notices

Human Gastric Function: An Experimental Study of a Man and His Stomach. By Stewart Wolf, M.D., Assistant Professor of Medicine, Cornell University Medical College, New York, and Harold G. Wolff, M.D., Associate Professor of Medicine, Cornell University Medical College. With a foreword by Walter B. Cannon, M.D. Oxford Medical Publications. Second edition. Cloth. Price, $5. Pp. 262, with 56 illustations. Oxford University Press, 114 Fifth Ave., New York 11, Amen House, Warwick Sq., London, E. C. 4, 1947.

This volume is an important contribution to the science of physiology and medicine and therefore is of interest to physicians. The main part of the book is a prolonged study of all phases of gastric functions (particularly on the influence of emotional states) on Tom, an adult man with complete closure of the esophogus (through accidental corrosion in childhood) and permanent gastrostomy. This is the third classic study on such patients, the earlier ones being the work on Alexis St. Martin by Dr. Beaumont and by Dr Carlson on Mr. V. The most significant new data in the present study are the changes (partly unpredictable) in gastric secretion, gastric acidity and gastric motility induced by varying emotional states. This is of particular interest to gastroenterologists in view of the increasing indications that nervous factors (mainly via the vagus nerves) are significant in the genesis chronicity and cure of gastric and duodenal ulcers. This edition includes three new chapters (v, VIII, XII). These contain further data on Mr. Tom, relevant studies on soldiers in the last war (chapters v and VIII) and a brief study on 1 peptic ulcer patient before and after sectioning of both vagus nerves at the level of the diaphragm (the Dragstedt operation for chronic peptic ulcer). This patient was also subjected to gastrostomy. The authors conclude that the vagus nerves are not necessary for the gastric hyperemia following a meal, but these nerves do carry impulses concerned in the production of gastric hyperfunction as a reaction to certain emotional states.

Whither Medicine: From Dogma to Science? By Antony Fidler, M.D. Cloth. Price, 6s Pp. 115. Thomas Nelson & Sons, Ltd., Parkside Works, Edinburgh 9, 1946.

This book purports to be a proposal for the making over of medicine into an exact science with a new system of diagnosis, prognosis, treatment and research. It is supposed to be "a closely reasoned challenge to the orthodox scheme of medical theory and practice." The author has been dozent at the University of Warsaw and is senior lecturer in medicine in the Polish School of Medicine in Edinburgh. Obviously a book designed to win converts to a new type of medicine should show clearly what is wrong with the old methods and what is very attractive and logical about the proposed new one. Actually, one reads much in this volume without getting any understanding of the writer's views. The book appears to be an example of what David Starr Jordan used to call sciosophy, or the shadow of wisdom. The text looks scientific, but when one tries to get any meaning out of it one is stumped.

Stepping Stones Towards the Future. Twenty-Seventh Annual Report of the National Bureau of Economic Research. By Arthur F. Burns, Director of Research. Paper. Pp. 91. National Bureau of Economic Research, Inc. 1819 Broadway, New York 23, 1947.

If economic history is a stepping stone to our economic future, a critical examination of the role of business cycles in the business life of the United States can prove illuminating. A business cycle is a unique historical phenomenon, but its characteristics have been substantially uniform in the long run. If depressions are becoming steadily more severe, if business cycles have undergone structural or secular changes, these trends have not become evident from the statistical records of the National Bureau of Economic Research.

Using the business cycle as a frame of reference, economists associated with the National Bureau are subjecting almost every aspect of our business life to statistical analysis. This report of the work of the National Bureau contains, in addition to the introductory remarks on business cycles and the long run economic outlook, summaries of the work now in progress in the many related fields of economic research. For example, the work going forward under Simon Kuznets, Jacob Marshak and Morris A. Copeland on various aspects of national income and the flow of money is described briefly by these men. Employment and productivity are similarly treated by Solomon Fabricant and George Stigler. Special attention is here given to the upward trend in employment in service industries. In this connection Mr. Burns cites a contrasting trend in employment in medical service: ". . . the number of physicians [in the United States] was 157 per 100,000 persons in 1900 and only 133 in 1940." Employment in government has grown twice as rapidly from 1900 to 1940 as total civilian employment. Exclusive of the armed forces and persons on relief projects, public employees rose proportionately from 4.5 per cent of all workers in 1900 to 9 per cent in 1940. By July 1946 one out of every ten employed persons was on a government pay roll.

The work on business cycles is described in great detail. Analysis of time series, cyclical movements in transportation and communications industries, in consumer goods industries and in agriculture receive specific comment. Other topics which are being studied by the members of the National Bureau of Economic Research include commodity prices and their cyclical behavior, the labor market, its wages and the changes in its size and composition, fiscal policy and banking and finance.

These progress reports can be compared to "coming attractions," and the books and monographs which will be published this year by the bureau should prove to be eminently worth while as reliable and valuable contributions to our store of economic data.

Gynaecological Endocrinology for the Practitioner. By P. M. F. Bishop, D.M., Clinical Endocrinologist, Guy's Hospital, London. Cloth Price, $2. Pp. 121, with 2 illustrations. William Wood & Co., Mt Royal & Guilford Aves., Baltimore 2, 1946.

This small handbook on the endocrine aspects of gynecology was written primarily for the general practitioner. It attempts to explain the mechanisms of the various endocrinal disorders and to suggest the use of the appropriate hormonal preparations. The author hopes thereby to dispel the mysticism of this special field and to remove the practice of medicine from the pharmaceutical companies, their publications and the detail men. To this end he discusses briefly the menstrual cycle, the various sex hormones and their administration, amenorrhea, excessive bleeding, dysmenorrhea, infertility, pregnancy and the various pregnancy tests and hormone assays. He concludes with an extensive appendix in which are listed the commercial hormonal preparations. Although the book sketches the barest details of a wide field of medical knowledge, it can be recommended to the general practitioner.

Radium Lost and Found. By Robert B. Taft, M.D., B.S., M.A. With an introduction by George E. Pfahler, M.D., Sc.D., LL.D. Second edition. Cloth. Price, $2. Pp. 158, with illustrations by Mercedes Hoshall. B.F.A. The Author, 103 Rutledge Ave., Charleston 16, S. C., 1946.

This volume is a compilation of interesting factual accounts about the loss of therapeutic radium and the search for it. Many authenticated stories are recorded relating to the ingenuity of individuals who have devised ways and means for recovering lost radium. The book was originally written by the author for private distribution among his colleagues and friends. It was so well received that the second edition was published. The book is of value to physicians, nurses and technicians who handle radium because it provides a voluminous source of ideas for any one who may be called suddenly to search for radium which has been carelessly misplaced, lost or stolen.

The 1946 Year Book of Obstetrics and Gynecology. Edited by J. P. Greenhill, B.S., M.D., F.A.C.S., Professor of Gynecology, Cook County Graduate School of Medicine, Chicago. Fabrikoid. Price, $3.75. Pp. 655, with 109 illustrations. Year Book Publishers, Inc., 304 S Dearborn St., Chicago 4, 1947.

The 1946 Year Book of Obstetrics and Gynecology is typical of the many previous editions. It contains an excellent and rather complete selection of abstracts of the year's literature in this special field. Numerous pertinent editorial comments add much to the value of the abstracts, for the author has had wide experience in obstetrics and gynecology. The Year Book is a valuable digest of current literature and can be read with profit by students and practitioners.

The Postnatal Development of the Human Cerebral Cortex. Volume III: The Cortex of the Three-Month Infant. By J. LeRoy Conel, Professor of Anatomy, Boston University School of Medicine, Boston. Cloth. Price, $12.50. Pp. 158, with 220 illustrations. Harvard University Press, Cambridge 38, Mass.; Oxford University Press, Amen House, Warwick Sq., London, E. C. 4, 1947.

This is the most important of the series of monographs on the structure and development of the cortex of infants. In the first volume the conditions at birth were described. In the second those at one month were considered. The present volume deals with the cortex at about 3 months. It is based on a thorough study of 6 normal well preserved brains. The forty most significant areas of Economo and Koskinas are described and illustrated on the basis of preparations by the Nissl, Cajal, Golgi-Cox and Weigert methods. Low power photomicrographs of the first three accompany each description together with splendid drawings of representative cell types from the pen of Miss Piotti selected from the Golgi-Cox material. In addition to these ninety-eight plates there are six plates of photographs from Weigert preparations of the more important areas. The counts of cell density and measurements of cell size are based on paraffin sections, and one would like to know how much greater the shrinkage was in the earlier stages and how it compares with the adult conditions.

In a chapter which the author modestly entitles "Comments" he presents the developmental changes found in his studies of prenatal as well as postnatal stages. He lists nine criteria of differentiation, viz. the width of the cortex and of its several layers in Nissl preparations, the size of the various cell types and the number of nerve cells per unit area, the differentiation of the Nissl bodies and neurofibrils, the form and structure of the dendrites, the appearance of artefacts like "thorns" and the development of exogenous fibers and of myelin. All these characters indicate that area FA (Brodman's area 4) leads all others in differentiation. It is closely followed by the postcentral afferent areas (PB and PC), the auditory area of the transverse temporal gyri (area TC) and the striate area (OC) in the order mentioned. It is rather surprising that the hippocampal area lags behind the others, since the hippocampus is the first region of the cortex to differentiate in development (Hines). It is to be hoped that this magnificent material will yield further details of cortical development. All concerned with the production of these beautiful volumes have earned the gratitude of those who are interested in the structure of the cerebral cortex.

Traité d'hygiène. Tomes I et II. Publié sous la direction de A. Rochaix, professeur d'hygiène à la Faculté de médecine et de pharmacie de Lyon, Lyon, P. Sédallian, professeur de clinique des maladies infectieuses et de bactériologie à la Faculté de Lyon, et R. Sohier, professeur agrégé du Val-de-Grâce, chargé des fonctions d'agrégé d'hygiène à la Faculté de Lyon. Paper. Pp. 1098, with 199 illustrations; 1099-1898, with 133 illustrations. Masson & Cie, 120 Boulevard Saint-Germain, Paris 6^e^, 1946.

This two volume "treatise on hygiene" includes in its 109 chapters not only the materials of hygiene as we know them but also those of preventive medicine, public health, sanitation and epidemiology. It is obviously written as a reference work and is well classified and indexed. The illustrations are carefully chosen and add much to the usefulness of the treatise.

Volume I includes population problems and demography, atmospheric and climatic factors, personal hygiene, infant hygiene, alimentation, rural hygiene, urban hygiene, industrial hygiene and the hygiene of transportation. Chapter III, on the causes of the depopulation of France, chapter XV, on the minimal diet, chapter XXIX, on hospitals and hospital hygiene, and section IX, on the hygiene of transportation, contain much that is new and of particular interest.

Volume II includes sections on general epidemiology, epidemiology of diseases of known bacterial causes, epidemiology of diseases of virus or unknown causes, epidemiology of parasitic diseases, "the great social scourges," and legislation, administration and organization in the field of public health and sanitation. Of unusual interest is section XIV, dealing with the measures to combat alcoholism, tuberculosis, the venereal diseases, cancer, rheumatism and abnormal heredity.

The three editors and nine collaborators in the treatise are to be congratulated on a workmanlike job well done. It is too bad that such a work could not have been dignified by cloth covers, machine cut pages and more impressive illustrations.

Dr. Samuel Guthrie, Discoverer of Chloroform, Manufacturer of Percussion Pellets, Industrial Chemist (1782-1848). By Jesse Randolph Pawling, M.D., M.A., F.A.C.P. Cloth. Price, $3.50. Pp. 123, with illustrations. Brewster Press, Trust Co. Bldg., Watertown, N. Y., 1947.

The appearance of this little volume is a very opportune contribution to the hundredth anniversary of chloroform. Samuel Guthrie moved to the neighborhood of Sackets Harbor in 1817 and first made chloroform in his private chemical laboratory there in 1831. As a citizen of this neighborhood, Dr. Pawling has utilized interviews with descendants, letters and newspaper clippings to bring to light much more information than was previously available about Guthrie and his scientific contributions. He appears to have verified Guthrie's priority in the manufacture and purification of chloroform. At the same time a brief but interesting story is told of Dr. Guthrie's commercial activities, his family life and something of the history of "Upper New York State" during the first half of the nineteenth century. The book is a worthy contribution to one phase of the history of surgical anesthesia, but in addition it should prove interesting to both laymen and physicians as a brief and well told story of significant pioneer accomplishment.

Atlas of Histopathology of the Skin. By G. H. Percival, M.D., Ph.D., F.R.C.P.E., Grant Professor of Dermatology, University of Edinburgh, Edinburgh, A. Murray Drennan, M.D., F.R.C.P.E., F.R.S.E., Professor of Pathology, University of Edinburgh and T. C. Dodds, F.I.M.L.T., F.I.B.P., F.R.P.S., Laboratory Supervisor, Department of Pathology, University of Edinburgh. Cloth. Price, $16. Pp. 494, with 376 illustrations. William Wood & Co., Mt. Royal & Guilford Aves., Baltimore 2, 1947.

This atlas is the product of cooperation between dermatologist, pathologist and experts in technic. The microscopic structures of the more frequent skin diseases are portrayed in colors with only short explanations and without any discussion of the literature. The illustrations are uniformly of a high grade of workmanship and are provided with good descriptive legends. The stain and the magnification are given in each case. Photographs are reproduced of fleas and other insects of special interest to the dermatologist. Presumably on account of their rarity in Scotland, blastomycosis and other fungous infections of the skin are not illustrated. The atlas will be an excellent guide in the study of the histopathology of the skin.

If You Need an Operation. By Richard A. Leonardo, M.D., Ch.M., F.I.C.S. Cloth. Price, $3. Pp. 198. Froben Press, 4 St. Luke's Place, New York 14, 1947.

The whole question of the value of this book lies in the point of view of the reader. It is a detailed description of surgical technics for the patient. It starts out with preparations for the operation, discussion on the procedure itself, and the aftermath. It then goes into detail about the surgery of the appendix, gallbladder, hernia, stomach, intestine, rectum, uterus, ovaries, vagina, goiter, breast, chest, brain and the urinary system. It closes with a chapter entitled "What About the Future?" which is a condensed outline of hygienic living in the postoperative era. If the doctor thinks his patient ought to have detailed information as to the operative technic, including the names of the instruments, and how many assistants the surgeon needs in the operating room, this is a good book. If the physician holds the opposite view, he will not recommend it to his patient.

The Doctor's Scrapbook. By J. W. Torbett, Sr., B.S., M.D., F.A.C.P. Cloth. Price, $2.50. Pp. 258, with 7 illustrations. The Author, 302 Houghton Ave., Marlin, Texas, 1947.

This is an interesting and revealing book which is exactly true to its name. It has no organization, plot or plan. It is full of verses and jingles which the doctor has written for his own amusement and for that of his family, friends and patients. He tells about his life, giving the most inconsequential episodes but creating out of them the impression of an earnest, kindly and sincere gentleman who has given everything he has to the practice of medicine, the service of his patients and to gracious living in a wide circle of friends and acquaintances. If the jingles and verses never reach the status of poetry, and if one does not always agree with the medical ideas expressed, one can nevertheless appreciate this book for its warm, human sincerity and the picture it gives of the kind of doctor who has patients who love and revere him through a long lifetime and far beyond.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

HAY FEVER INOCULATIONS AND HEART DISEASE

To the Editor:—The question has arisen and a dispute has ensued between the allergist and the internist as to whether or not hay fever inoculations can cause heart disease and also whether or not such injections can be injurious to those who have recovered from such heart conditions.

M.D., New York.

Answer.—Inoculations with pollen to prevent hay fever do not contribute in any way that we know of to heart injury. There should be no objection to giving such injections to those who have recovered from any heart condition, provided precautions are taken to prevent an overdose of pollen, which might produce a systemic reaction. The systemic reaction may be severe. In patients with extensive heart damage from any cause such a reaction may be of greater danger than in the normal person. In addition it may be necessary to use epinephrine to counteract a systemic reaction. This might be contraindicated in older patients who have had coronary thrombosis or in patients with hypertensive heart disease.

HYPO-OVARIA

To the Editor:—The hair of a woman aged 28 is absent beneath the arms and around the pubic area. She has never menstruated. The lower measurements are greater than the upper, i. e. symphysis to toes and symphysis to head. Her stretch from finger to finger is greater than her height. She is not obese but gives one the impression of a pituitary type by her large frame and slight spacing between the teeth. Is one justified in using endocrines? I have suggested extensive studies of blood and urine estrogens and ketosteroids, but feel that the cost is prohibitive. Have you any suggestions?

M.D., Connecticut.

Answer.—From the foregoing description the patient should have had hypo-ovaria present since childhood. However, knowledge of exact measurements, development of the breasts, weight and pelvic findings would aid in confirming this impression. Whether the hypo-ovaria is primary or secondary to anterior pituitary deficiency can be determined with certainty only after considerable study. Hypothyroidism, hypoadrenocorticism and a short stature are evidence suggestive of diminished anterior pituitary function. Their absence would increase the probability of the failure being primarily ovarian, although deficiency of the pituitary gonadotropic principle alone is possible. However, short stature may be associated with a *primary* ovarian failure. Determination of the basal metabolic rate would help exclude pituitary myxedema, but hypoadrenocorticism can be excluded with certainty only by the finding of low 17-ketosteroid excretion and a negative reaction to a "water test." However, if the patient is vigorous and strong and does not have abnormal pigmentation of the skin or mucous membranes, hypoadrenocorticism is unlikely. Pituitary tumors such as craniopharyngioma are frequently a cause of hypopituitarism; their exclusion may be aided by roentgenograms.

The assay for gonadotropins of several twenty-four hour specimens of urine collected at intervals of four to seven days would be the best single method for differentiating primary from secondary hypogonadism. In primary ovarian failure there is a normal or increased urinary excretion of gonadotropins, while in failure secondary to pituitary deficiency the excretion is diminished. Criteria for normal excretion vary with the laboratory and the method used for estimation.

Treatment for hypo-ovaria is generally considered to be unsatisfactory. If the epiphyses are closed, nothing can be done to change bodily proportions. It would be extremely unlikely that a normal menstrual cycle could be induced in this patient by any endocrine therapy. No preparation of pituitary or pituitary-like hormone capable of stimulating the human ovary to produce estrogens and progesterone in anything like a normal manner is available. Therefore for purposes of therapy it matters little whether the patient has primary or secondary hypo-ovaria. The treatment is the same in the two instances, by "endo-organ" therapy.

Administration of estrogens with or without progesterone in a cyclic manner may produce uterine bleeding. Whether this is desirable depends on the preference of the patient. A feeling of increased well-being may result from the administration of estrogens, and a trial of such therapy should be carried out.

ACHLORHYDRIA

To the Editor:—What is the present day concept of the absence of free hydrochloric acid in the gastric juice? Are people who eat vegetable diets (raw) more apt to have achlorhydria than those who eat meats? Should a man aged 50, entirely free of gastric symptoms, be given diluted hydrochloric acid? Is achlorhydria associated with presenile arteriosclerosis? Any information on the general subject of achlorhydria gastrica will be appreciated.

M.D., District of Columbia.

Answer.—There is no evidence to suggest that the ingestion of vegetables may produce achlorhydria or that meat in the diet prevents it. A person aged 50 years, free of gastric symptoms, should not be given diluted hydrochloric acid. It has been shown that in the ordinary dosages of 10 to 15 drops three times daily diluted hydrochloric acid does not increase the p_H of the gastric juice to any appreciable degree. Therefore it is unlikely that any rationale exists for administering the acid to any patient, regardless of symptoms or degree of acidity. An exception may be made for psychotherapeutic reasons.

Achlorhydria is construed to be synonomous with anacidity after histamine stimulation (0.1 mg. to 10 Kg. of body weight). This condition occurs in approximately 10 per cent of the general population, somewhat more often in the older age groups, 60 per cent in patients with gastric carcinoma, and in all cases of pernicious anemia. In 100 consecutive cases of gastric anacidity, Bloomfield found 54 asymptomatic.

Although presenile arteriosclerosis and anacidity may be occasionally concomitant, evidence to show a causal relationship is absent.

There does, however, seem to be some relationship between the development of anacidity, atrophic gastritis, pernicious anemia and gastric carcinoma. This is supported by (1) the observation that atrophic gastritis, demonstrated both gastroscopically and by histologic section, occurs with great frequency in pernicious anemia; (2) gastric carcinoma is sometimes preceded by atrophic gastritis; (3) gastric carcinoma occurs more frequently in patients with pernicious anemia than in the general population. On the other hand (1) many patients with carcinoma of the stomach have an otherwise normal gastric mucosa; (2) atrophic gastritis is frequently a transient finding, with normal acid secretory power of the gastric mucosa; (3) numerous achlorhydric patients are entirely asymptomatic and never develop atrophic gastritis, pernicious anemia or gastric carcinoma.

Gastric achlorhydria (histamine anacidity) is not a disease entity and does not require treatment per se. When the condition is demonstrated, effort should be made to rule out the presence of pernicious anemia and gastric carcinoma.

AMINO ACIDS FOR ARTHRITIS

To the Editor:—A patient claims that amino acids have aggravated an arthritic condition. Can you give me any information? I have been unable to find anything definitely for or against this theory.

Louis L. Sherman, M.D., Oakland, Calif.

Answer.—It is impossible to answer this question adequately because the correspondent did not state what kind of arthritis the patient had, what was the nature of the supposed articular aggravation, how long after the administration of the amino acids the aggravation occurred, what preparation of amino acid was used and how it was given, and whether or not the patient was an allergic individual.

In 1943 Carlström and Lövgren of Stockholm recommended the treatment of "chronic polyarthritis" with adenosine triphosphoric acid: of 17 patients so treated fifteen "were definitely improved or recovered." Adenosine triphosphoric acid was found to be superior to muscle adenylic acid. Further studies were reported in 1945 by Lövgren. This work has not yet been confirmed. Reports by American workers on the use of amino acids for chronic arthritis have not been found.

In rheumatoid arthritis the total serum proteins are generally normal in amount; the fibrinogen is generally increased; the serum globulin is normal or slightly increased; the serum albumin is normal or slightly decreased, occasionally slightly increased; the albumin-globulin ratio is generally reduced below normal values.

TIME OF HEALING OF FRACTURES

To the Editor:—For the past five years I have noted a tremendous increase in the time it takes for fracture to heal. If this had been in old people particularly I would not have been so surprised, but it has occurred just as much in the young and middle aged. One youngster, aged 12 years, had a simple fracture of the middle third of the tibia. It took from September 1 to January 1 to heal. I had a talk with the roentgenologist, who states that it had also been observed in other hospitals. Has there been any comment in the current literature about this? Have there been any studies on this subject?

M.D., Pennsylvania.

ANSWER.—There has been no change in time required for the uniting of fractures recorded in surgical reports.

Certain factors lead to longer periods of healing time of fractures. In children fractures usually unite quickly and promptly —a fractured femur in a newborn infant may have a firm abundant callus in a week. Other factors at any age, such as poor general health, malnutrition, insufficient activity, calcium and phosphorus deficiencies in disease or senility, local interpositions and insufficient reduction and immobilization may alter the healing time. Operative intervention may influence the healing time, in some instances hastening it because good reduction is obtained, in other instances delaying it because of loss of normal blood extravasation about the fracture evacuated at operation or as the result of electrolytic action of implanted metals, or infection.

There is also a difference of healing time in different persons. The case of the child cited may have been governed by one or many factors involving the child's state of health and the method of treatment applied. Incised operative wounds do not all heal by first intention; some become keloid, some break open or even ulcerate. Bone wounds, although buried in tissue, go through similar variations, but the average normal rate of healing remains as it has always been when not interfered with.

The correspondent may also consider the difference between clinical healing with a satisfactory palpable or supporting callus which permits starting use and function and healing as demonstrated roentgenologically, which requires a much longer time before there is full calcified cementing callus between fragments. Possibly he is now using x-ray examination to a greater extent to determine full and final bony union; hence the apparent lengthening of time for uniting.

HAZARDS OF TRICHLORETHYLENE

To the Editor:—I should like some information on trichlorethylene when used as a degreasing agent. How much vapor is created on exposure to air? (The tank is uncovered.) How toxic is the material to a person in a room that is about 35 feet square with a 12 foot ceiling if he is at the opposite end of the room and also within eight feet of it? There is no exhaust fan in the room. What possible diseases can be contracted when exposed to these fumes?

Jack G. Lustgarten, M.D., Merrick, L. I., N. Y.

ANSWER.—Too many factors are involved in this situation to permit categorical answers to the questions. The amount of vapor evolved will depend on the adequacy of the water jacket around the degreaser, the size of the degreaser, the volume of trichlorethylene involved and the temperature utilized. A single milligram of trichlorethylene entering the air will produce 187 parts of vapor in a million of air, which is just about the beginning of the harmful zone (200 parts per million being the maximum permissible concentration for sustained exposure under the American Standards Association code). Only a few milligrams of trichlorethylene continually thrust into the atmosphere could lead to undesirable exposure. The fact that the tank is uncovered is not highly significant if the tank is water jacketed for condensation purposes. However, experience has shown that many large tanks require exhaust systems for reasons of protection in addition to the water jacketing. Just how toxic trichlorethylene may be to someone working in a room of the dimensions specified depends entirely on the quantity of vapors emitted by the degreaser with due consideration for dilution in the work room atmosphere. Should there be sufficient exposure, trichlorethylene poisoning may arise, which in its mildest form may be characterized by nausea and vomiting and in severer form by significant damage to the liver and kidneys. A proper procedure under the circumstances is to procure laboratory determination as to the concentration of trichlorethylene vapors at various places in the work room and under various circumstances. The Industrial Hygiene Bureau of the New York Department of Labor is well equipped and experienced to make determinations of this character.

TREATMENT OF NEUROSYPHILIS

To the Editor:—Please given an evaluation of tryparsamide in the treatment of neurosyphilis and at the same time let me know whether the use of mapharsen appears to be more advisable in combination with bismuth as follow-up treatment after fever treatment than tryparsamide and bismuth.

Werner Lonsen, M.D., Chicago.

ANSWER.—The consensus of most syphilologists at present is that tryparsamide is of little or no value in the treatment of neurosyphilis and that whatever value it has is more than overshadowed by the risk of damage to the optic nerve and vision. The drug has been abandoned in many large syphilis clinics in the country for the last several years.

As to the relative merits of mapharsen plus bismuth and tryparsamide plus bismuth as follow-up chemotherapy after the fever treatment of neurosyphilis: the latest available evidence indicates that fever therapy alone without following chemotherapy with any drug accomplishes almost as much as with such chemotherapy. This is certainly true if by "fever therapy" the inquirer means induced tertian malaria, which is the most desirable form of fever treatment. The most recent information is to the effect that fever therapy (induced tertian malaria) combined with the simultaneous administration of penicillin will accomplish as much in the several types of neurosyphilis and within a period of five weeks as was previously accomplished by fever therapy with two to three years of following chemotherapy. This suggestion, if backed by further evidence, will mean an enormous saving of time and expense to the average patient with neurosyphilis.

EFFECTIVENESS OF BOOSTER DOSE OF TETANUS TOXOID

To the Editor:—What is the maximum lapse of time between injections of tetanus toxoid that a booster dose will be effective?

M.D., Providence, R. I.

ANSWER.—It is supposed that basic immunity (the ability of the body to respond to a booster dose of tetanus toxoid) is lifelong. However, the available data indicate that a patient will produce tetanus antitoxin in response to a booster dose of tetanus toxoid as long as five to six years after initial immunization with tetanus toxoid. The maximal duration of basic immunity is the subject of long-term study in several American clinics, and the results will be reported from time to time.

The response to tetanus toxoid is characterized by four features: 1. Acceleration: A high level of antitoxin appears in seven days or less, thus providing adequate immunity in the event of short incubation periods. 2. Augmentation: The antitoxic level after the booster dose is remarkably increased, sometimes to levels as high as fifty to one hundred times those present at the time of recall injections. 3. Prolongation: The duration of antitoxic immunity is more persistent than that evoked by the previous injections. 4. Facilitation: The body responds to minute doses of tetanus toxoid. Thus, a recall injection of but 0.1 cc. (fluid or alum precipitated tetanus toxoid) elicits a satisfactory immunologic response.

There are circumstances under which antitetanic serum (passive immunization) has been recommended instead of a booster dose of tetanus toxoid (active immunization). In the presence of severe hemorrhage, poor general health, diseases of a debilitating nature, severe or multiple injuries or delay in the injection of tetanus toxoid, the use of adequate doses of antitetanic serum (10,000 or more units) is justified. There is a difference of opinion concerning this particular problem, so that failure to employ tetanus antitoxin under these circumstances cannot be interpreted as an act of negligence.

ROUTE OF INFECTION IN VIRAL PNEUMONIA

To the Editor:—What is the consensus regarding the primary infection of viral pneumonia other than through the upper respiratory system? Are there any cases on record in which it is thought that viral pneumonia was contracted by entry of the virus through the skin from insect bites?

T. A. Taylor, M.D., Lufkin, Texas.

ANSWER.—The epidemic forms of viral pneumonias and the pneumonias of influenza, measles and chickenpox are acquired chiefly, if not always, by the airborne route. Hand to mouth infection and infection from dishes or other articles soiled with exudate from patients also may be possible. If the pneumonias of the psittacosis group of agents are considered as viral pneumonias, the rare pneumonia of venereal lymphogranuloma, a member of the group, may be venereal in origin. There are no cases on record in which pneumonias were proved to arise from infections by way of the skin. Transmission by insects was suspected in a group of cases among American soldiers stationed in India, but the idea was abandoned for lack of evidence.

CANCER OF THE UTERUS

EMIL NOVAK, M.D.
Baltimore, Md.

The problem of gynecologic cancer, as represented most conspicuously by cancer of the uterus, is only one aspect of the general problem of the disease which has so long challenged the members of the medical profession. Great advances have of course been made, but the grim citadel of cancer still looms ahead, not untouched but certainly not conquered. Until the latter part of the last century the brunt of the attack had been borne by clinicians, but with the developments which flowed from Virchow's establishment of cellular pathology reinforcements then came from the ranks of the pathologists. It was not long before pathologists became familiar with those microscopic characteristics of cancer which explain its destructive clinical course. These new concepts were promptly applied by surgeons in their elaboration of the surgical attack on the disease, which had to take cognizance of such attributes of cancer as infiltration and extension, lymphatic invasion and metastatic dissemination.

In the immediate problem of uterine cancer as well as in other surgical aspects of cancer much was accomplished, and innumerable patients were saved who previously would have been doomed. But a limit was finally reached beyond which surgical procedures could not go. This restrictive barrier still confronts the surgeon today, in spite of the relatively minor improvements made possible by such modern surgical adjuvants as transfusion, chemotherapy and antibiotics. I do not believe that any gynecologist who passed through the early days of radical surgical intervention for cancer could have experienced any great enthusiasm for it, even though it was the only method available to him for the salvage of at least a fraction of his patients.

Small wonder, therefore, that the advent of radium was welcomed, first as an agency for palliative therapy, later as an alternative primary weapon of attack. Thus the brilliant discovery of radium by the Curies in the field of physics found a life-saving application in the treatment of human disease, another of the innumerable illustrations of the interdependability of all branches of science. In the treatment of uterine cancer a full generation has been devoted to the evaluation of the relative importance of surgical procedures and radium therapy, and the final answer has not yet been reached. The problem has been a much more difficult one than the appraisal of certain other modern weapons in the treatment of disease, such as insulin or chemotherapy. The nature of cancer, with its long and varied clinical course; the imperfections of standardization in histologic and clinical studies; the difficulties and the long years required to test the efficacy of various plans of treatment, all these have made the process of crystallization of opinion and practice exceedingly slow indeed.

But in the meantime the warfare on cancer in general has assumed the all-out proportions of that characterizing the belligerent nations of World War II. All the forces of science have been marshaled against it—clinicians, chemists, biologists, biochemists, physicists, endocrinologists, geneticists, plant pathologists and workers in still other fields. The chief objective has been determination of the cause of the disease, but it is not impossible that a cure may be found before the cause is discovered. In spite of the great accomplishments of both surgical practice and radiotherapy, many surgeons must consider that these are weapons of expediency, temporary makeshifts which must be utilized to the fullest possible extent until some more direct and more fundamental weapon, some atom bomb of cancer therapy, is made available.

The purpose of this paper is a survey of the cancer problem from the camp of the gynecologists, who have long been among the shock-troops in the anticancer warfare. It will be concerned more particularly with the immediate problem of cancer of the uterus, the most important one confronting gynecologists today. Its importance is illustrated by the fact that no less than 17,152 women died of this disease in 1944, the last year for which complete figures are available. That no conspicuous impression has as yet been made on mortality due to cancer is indicated by the fact that the total deaths from this cause in 1941 numbered 16,516, with 16,393 in 1942 and 16,968 in 1943. Furthermore, cancer has advanced to second place as a cause of death in the United States, being topped only by cardiac disease. Since this is not to be a statistical paper it includes no discussion of various qualifying factors, such as the fact that life expectancy has been so greatly increased in the present day that a much larger proportion of persons reach the cancer age than formerly. Even with such ameliorating considerations the facts on the incidence and mortality of cancer are bad enough to constitute a continuing challenge.

Since this discussion is directed to the general practitioner as well as to the gynecologist, it has seemed best to subdivide it as follows: (1) a brief comment on cancer research, especially as it bears on pelvic cancer in women; (2) newer developments in the pathologic study of uterine cancer; (3) newer methods of diagnosis of uterine cancer, and (4) the present status of treatment. It is obvious that any attempt to survey

---

Read in the General Scientific Meetings at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 10, 1947.

such a vast field must be in the nature of a summary and that it is open to the criticism of the individual factor in evaluation, though this will be avoided as far as possible.

RESEARCH IN CANCER

This is not the place, nor am I qualified, to review the far flung studies directed toward a solution of the riddle of cancer, for riddle it still is in spite of the efforts of so many able investigators on so many different fronts. Nor are there many who can envisage the whole problem in all its aspects. However, there are a few observations which seem justified as to general trends in the concept of the nature of cancer, and a few which seem especially pertinent to the immediate problem of uterine cancer.

There is a growing conviction that the cause of cancer is intracellular, rather than an extrinsic factor such as a virus. The somatic mutation which changes the normal body cell to the cancer cell, however, is not completely independent of extrachromosomal factors. In spite of the enormous amount of investigation on the metabolism and growth characteristics of cancer cells as contrasted with normal cells, pathologists are still completely in the dark as to the inciting factor which transforms the well behaved normal cell into the gangster cell of cancer. Whether this mutation affects a single cell or considerable groups of cells is not certain, but the latter seems more probable in view of the occurrence of multicentric and multiple growths.

For many years pathologists have insisted that cancer is not a single disease but a whole group of diseases. Certainly there are wide variations in histologic type, and certainly there are differences in the mechanism of production of different cancers, but it is difficult to avoid the impression that a common denominator does exist. When any one variety of cancer is really completely explained, the pieces of the whole jigsaw puzzle will probably fall quickly into place.

As to such factors as heredity, one does not have to accept the much criticized observations of Maud Slye to feel that the genetic factor must be of great importance in the transmission not of cancer but of predisposition to cancer from one generation to succeeding ones. Even sharp critics of Slye's conclusions are apparently willing to concede this, though there still exist differences in opinion as to the relative roles of genetic factors, and of such extrinsic factors as chronic irritation, whether traumatic, inflammatory or hormonal. The genetic predisposition is apparently so strongly developed in some persons that cancer will arise even without any extrinsic irritation. In others it is less well defined, so that the predisposition plus an extrinsic factor is necessary for the development of the disease. Finally, the genetic factor in still other persons is so weak that cancer is unlikely to develop regardless of the degree of local irritation. It would be difficult to convince any clinician of large experience that heredity plays no part in cancer and that the relatively frequent instances of familial tendency toward cancer are to be explained entirely on the basis of coincidence. Macklin's convincing statistical studies[1] have given him strong support for his views.

The previous statements have an application to the clinical problem of cancer of the cervix. For many years gynecologists have been taught that chronic irritative lesions of the cervix predispose to the development of carcinoma, and this is still the prevailing view. However, a surprisingly large proportion of early cancers, in these days of intensive search for early lesions, have been found in cervices which grossly are normal or nearly normal. This, as a matter of fact, has been my own experience. But this does not negate the possible contributory role of chronic irritative lesions. It merely suggests that in certain persons the genetic predisposition to cancer is so strong that cancer develops without the contributory influence of chronic irritation.

HORMONES

Of especial interest to the gynecologist are the provocative studies of recent years as to the possible role of the ovarian hormones in carcinogenesis. As far back as 1918 Leo Loeb[2] concluded that the endocrine glands may be of importance in the development of cancer in those organs and tissues which are normally under the physiologic control of the ovarian hormones. This would obviously apply to the genital tract and the breast. After all these years this general statement still seems to be a valid one. The investigations of Lacassagne (1932),[3] which described the production by estrogens of mammary carcinoma in male mice of cancer susceptible strains, were the starting point of a long series of experimental studies on the carcinogenic effect of estrogens on the breast. While cancer has been produced in certain animals and strains, there would seem to be justification for the general conclusion that such results are not, as Gardner says, to be attributed to any chemical specificity for mammary carcinogenesis that cannot be associated with their estrus-producing capacity.

As regards carcinoma of the uterus, it does not seem to have been possible to produce actual carcinoma of the endometrium by means of estrogen therapy, though simple hyperplastic conditions are readily enough produced. The interesting studies of Lipschütz on the remarkable fibromatogenesis following the administration of estrogen in the guinea pig do not appear to be applicable to the problem of cancer or, for that matter, even to that of the cause of uterine myoma. More successful have been the experimental efforts to produce malignant epithelial growths in the cervix, especially in mice, as reported by Gardner and his associates.[4]

There has been much discussion as to the possible carcinogenic hazard to the human subject of the estrogen therapy so widely prevalent and so often abused. I believe it may still be said that no case of human cancer has been recorded in which the evidence for an estrogenic causation is unimpeachable. It is true that several cases of mammary and at least 1 case of endometrial carcinoma have been reported in patients who had received such therapy, but it is difficult to exclude the *post hoc ergo propter hoc* factor in evaluating such evidence. Moreover, patients have received enormous estrogen dosage, as much as many millions of units, without the development of cancer. However, so long as there is the slightest uncertainty on this point, and in view of the carcinogenic effects of estrogen in at least some animals and tissues, estrogen therapy should be held to a minimum or avoided altogether in patients who because of heredity or through the existence of some other factor may be considered to possess a predisposition to the disease.

A number of clinical observations seem to bear on this point. For example, Crossen and Hobbs[5] have called attention to the fact that a late menopause seems to be a predisposing factor to uterine adenocarcinoma. Again, Corscaden and Gusberg,[6] as well as Randall,[7] reported that the later incidence of adenocarcinoma among women who had previously been treated for functional menopausal bleeding was found to be three and a half times that occurring in other women. Finally, the possible predisposing influence of postmenopausal hyperplasia of the endometrium has been stressed by Novak and Yui,[8] Taylor[9] and others. All these observations are a basis for the assumption not that the estrogenic factor is actually the cause of cancer but rather that the estrogenic stimulation, like any other irritation, is of importance only when superimposed on the still unknown genetic factor.

NEWER POINTS OF VIEW ON PATHOLOGY

For many years the term precancerous has been used by clinicians, but not always with the same meaning. Some applied it to lesions which were thought to be merely predisposing, such as chronic irritation of the cervix. Since the vast majority of such lesions never become malignant, and since their predisposing role is questioned by some, such use of the term precancerous is obviously loose and undesirable.

Others, however, have employed this designation to indicate those lesions which histologically are of borderline type and which therefore offer great difficulty in microscopic diagnosis, with frequent differences of opinion among pathologists. However, they have always insisted that these lesions are not to be considered as representing stepping stones between benign and malignant lesions but that they either are or are not cancer, though one may not always be able to make a sharp distinction by use of the microscope.

It is probable that this point of view is still valid. The actual conversion of a body cell to one with the characteristics of full-fledged cancer, including invasiveness, is probably a brief process. Unfortunately, however, the histologic appearance of the actually cancerous cell may be identical with its appearance before it assumes invasive propensities. This is exemplified in the lesion which, under such designations as preinvasive carcinoma, intraepithelial carcinoma, carcinoma in situ and Bowen's disease of the cervix, has excited so much interest and discussion among gynecologists in the past. It had been described by Schauenstein[10] as far back as 1907 and by Pronai[11] in 1908, while Schottländer and Kermauner[12] in 1912 had called attention to the fact that such a preinvasive cancer zone is often seen at the margin of frankly invasive carcinoma.

Schiller,[13] however, deserves the chief credit for recognizing the importance of this preinvasive type of lesion as the forerunner of those which alone had in the past been considered cancerous, i. e. those which showed similar intraepithelial changes plus histologic evidence of invasion. The fact that he flatly called such lesions *beginnendes Karzinom* created no little controversy, since such a concept meant that one could no longer insist on either clinical or histologic invasiveness as essential to the microscopic diagnosis of carcinoma, basing this on the characteristics of individual cells alone. The confusion was all the greater because the follow-up study showed that in at least a small number of cases genuine invasive cancer developed later, though perhaps not for many years. In all, however, the total number of such cases available in the literature is still extremely small. The interest and the controversy engendered by Schiller's observations served an invaluable purpose in that they stimulated in all clinics a much more intensive search for very early cancer, and particularly for stages of the disease antecedent to histologic invasiveness. In the laboratory with which I am associated, for example, among 88 case specimens in November 1926 there were only 5 cervical biopsies. In the corresponding month of 1936 there were 31 cervical biopsy specimens among a total of 127 case specimens. But in November 1946 the number of cervical biopsy specimens had risen to 244 in a total of 401. There was a corresponding rise in the proportion of specimens from diagnostic curettage.

There has been a similar multiplication of cervical biopsies in most other clinics. The biopsy specimens of an earlier day were for the most part taken for the confirmatory diagnosis of lesions concerning which there was little clinical doubt. Now the majority of biopsies are done when accurate clinical diagnosis would be impossible otherwise, and in many instances the cervix presents an essentially normal appearance. This is a happy augury for the future, and already the yield in demonstrating extremely early unsuspected cancer as well as preinvasive lesions has fully justified this intensive concentration on the cervix. In this clinic many early and preinvasive lesions have been found, and a considerable group of these have been recently reported by Te Linde and Galvin.[14] These authors have emphasized that when preinvasive lesions are found, further study of repeated biopsy specimens or of tissues obtained after either partial or complete removal of the cervix, or after hysterectomy, will almost always show definite invasiveness at some point or other, though there are some exceptions.

The impression which one gets from such observations is that cancer of the cervix may be a disease of extremely long duration, extending over perhaps as much as fifteen or twenty years, if both preinvasive and invasive stages of the disease are included. Many gynecologists, including myself, have in the past expressed doubt as to whether one could properly designate as real cancer the preinvasive lesion, which certainly possesses none of the clinical characteristics of cancer and which in this stage should be readily curable by simple excision. And yet there are few who have doubted that it is clearly related to cancer, repr at least a precursory stage. There are man angles of the subject which might be discussed, but I believe the available evidence at this time justifies the following conclusions, tentative though they must be:

[14] Te Linde, R. W., and Galvin, G.: Am. J. Obst. & Gynec 1944.

1. Preinvasive carcinoma is, as Schiller has maintained, actually the beginning stage of cervical carcinoma.
2. Cervical cancer, by this concept, may have a long history, divisible into two stages. The preinvasive stage is of extremely variable length; there may be no later development of clinical cancer, the patient dying of some other disease perhaps many years after the observation of the preinvasive lesion. The second stage, characterized by the break-through of the carcinomatous cells into the lymphatic vessels because of penetration of the basement membrane, marks the beginning of the clinically malignant stage of the disease.
3. During the preinvasive stage cancer is entirely benign clinically and is curable by simple complete excision.
4. When preinvasive cancer is revealed by cervical biopsy, further study will usually show definite invasiveness at some point, stamping the disease as genuine early cancer in its traditional sense.

In the body of the uterus as in the cervix one may encounter lesions which histologically if not actually present all stages of transition between obvious benign hyperplasia and adenocarcinoma. The term hyperplasia has always applied to the so-called Swiss-cheese pattern, which microscopically presents not the slightest resemblance to adenocarcinoma. Nor does it have any tendency toward malignant change during reproductive life, although some, including myself, believe that when it occurs as a result of postmenopausal estrogenic stimulation of the endometrium it may predispose toward malignant disease. The evidence for this has been presented in a paper by Novak and Yui.[8]

However, there is another hyperplastic condition of the endometrium, sometimes occurring only in limited areas of a Swiss-cheese endometrium but at times diffuse, which presents great difficulty in diagnosis and in which mistakes are often made. In this atypical variety of hyperplasia the epithelial and gland tissues show such decided proliferative and adenomatous change that the simulation of adenocarcinoma may be indeed striking. I have been much interested in these histologically borderline lesions, and Rutledge and I[15] have recently studied a considerable series of them. The crucial question whether such lesions are benign or malignant is what happens to the patient when only the most conservative treatment is employed, treatment admittedly totally inadequate for carcinoma.

We[15] have been able to show that many histologic conditions which are often diagnosed as adenocarcinoma are really only benign but highly proliferative atypical hyperplasias, which can be cured by the same simple measures applied to the ordinary Swiss-cheese variety. While experience will make one quite confident as to the correct diagnosis in the more moderate degrees of atypical proliferative hyperplasia, it has not been possible to draw any sharp histologic line between the extreme proliferative hyperplasias and real adenocarcinoma. As stated earlier in this paper, there is some point at which the cancer mutation takes place, but it is not always easy to determine this point histologically; hence, in the extreme degrees of atypical hyperplasia, with decided glandular atypia, epithelial overactivity and stratification, the simulation of adenocarcinoma is so perfect that one cannot, in the present state of clinical knowledge, afford to take the hazard of conservative treatment.

It is in regard to this disturbing group of cases that I have often quoted Josef Halban, an excellent pathologist as well as gynecologist, who, when I showed him such a slide during a visit to this laboratory, shrugged his shoulders and said *"Nicht Karzinom aber besser heraus!"* Since this entire group of cases has been fully described, with correlated clinical study, in the previously mentioned paper by Rutledge and myself, I shall not elaborate further on it here. We consider the subject of great importance not only in determining the fate of many individual patients but also in the vitiation of adenocarcinoma statistics and cure rates which results when benign lesions of this general group are incorrectly included as carcinomas.

NEWER METHODS OF DIAGNOSIS

Little need be said as to the method of colposcopic examination introduced by Hinselmann in 1927, because it has sharp limitations and it has never achieved any wide vogue in this country. It was, however, extensively employed in many European clinics and for that matter it is still employed in not a few, as attested by the recently published monograph of Wespi[16] from the Zurich Clinic in Switzerland. Those who have tried it know how time-consuming it is and will probably agree that it is valuable only as a screening method in ostensibly normal women.

Somewhat the same comment can be made concerning the tinctorial test of Schiller, which likewise has apparently been abandoned in most clinics. There seems to be general agreement that it has little value other than in suggesting promising points for biopsy in the search for exceedingly early stages of cancer in which there is no gross lesion. It is possible that it may be of some value in the cancer detection clinics, which deal with supposedly normal women, although most of them appear to have discarded the method. Not much will be revealed by the Schiller test that will not be apparent through minute examination of the cervix in the best possible light.

Still another diagnostic adjuvant has been much discussed since 1943, when Papanicolaou and Traut[17] published their monograph on the study of vaginal smears in the diagnosis of uterine cancer. They established beyond doubt that cancer is an exfoliative lesion and that it is possible to make the diagnosis of cancerous cells in the vaginal smear. A number of other authors, especially Meigs and his co-workers,[18] Warren and Gates[19] and Ayre,[20] have confirmed these observations. Here again there are certain limitations, the chief one being that only an expert cytologist can be expected to make reliable diagnoses from the single cells or small clumps of cells scattered in the multiform elements of the vaginal exudate. Even those most enthusiastic concerning their own results agree that for the present this diagnostic method cannot take the place of biopsy in the decisive diagnosis of cancer. Its chief function may prove to be that of a screening test in the search for cancer in large numbers of ostensibly normal women. One may perhaps dream of a day when women will be educated to send in vaginal smears to a central agency, perhaps a State Department of Health, manned by a battery of trained cytologists qualified to pass judgment on the specimens.

All these diagnostic aids have served a useful side purpose in that they have kept the minds of investigators focused on the search for decidedly early and therefore therapeutically highly favorable stages of cancer. The more cancer-conscious patients and physicians can be made on this point, the more the cancer cure rates will improve.

Biopsy still remains the one decisive diagnostic procedure, as it has been since Ruge and Veit more than sixty years ago established its value against the opposition of some of the outstanding gynecologists of the day. The criticism that it may result in dissemination of cancer cells is still often expressed, but the evidence for this has never been impressive. In fact a number of studies, such as the one of Wood[21] in 1919 and the recent one of Maun and Dunning,[22] present strong evidence against the supposed hazard of biopsy.

PRESENT STATUS OF TREATMENT

The treatment of cancer of the uterus, either cervical or corporeal, was practically stereotyped up to the advent of radium. The gynecologist had merely to decide whether the case was to be put into the operable or inoperable group, and in this decision it is easy to understand that the personal equation was an important one, based in no small measure on the conservative or radical tendencies of the gynecologist.

In cervical cancer there were some who considered operative intervention justified only in cases in which there was little or no infiltration of the vagina or broad ligament and no fixation of the uterus, and in which, therefore, the technical difficulties of the radical operative procedure did not seem too great. The general as well as the local conditions were taken into consideration then as now, so that a patient who was old and debilitated or decidedly obese, or who suffered with some serious general disease such as nephritis, myocarditis or diabetes, would probably be consigned to the group for palliative treatment. The gynecologist who was guided by such conservative considerations would select for operation only those cases in which there seemed to be (1) a reasonably good chance for cure and (2) and an excellent chance that the patient would pass safely through the ordeal of the extensive radical procedure which alone offered the possibility of cure but which carried with it a high rate of immediate mortality.

His bolder and more radical confrère would greatly extend the indications for operative intervention and contract the limits of such contraindications as have been mentioned, with the thought that such a fatal disease as cancer justified subjecting the patient to a greater hazard than would result from less serious elective procedures. Such a surgeon might operate on as many as 50 per cent of the patients with cancer, which was an extremely high figure when one considers the scarcity of really early lesions observed in those days. He would not infrequently come to grief, and those who remember the early days of radical operation will recall not only the technical difficulty involved in trying to eradicate a disease often much more extensive than had been anticipated but also the feeling of discouragement and futility which such cases so often left in the minds of the operator. The immediate mortality, even in the hands of the most expert surgeons, was expected to be high. For example, that of Wertheim, who devised the radical procedure which bears his name, was 12 per cent, and the figure was much higher in the hands of less experienced surgeons who attempted this formidable procedure. In addition these operations carried in their wake a whole array of such distressing sequelae as injuries to the bladder and ureter, often with resultant fistulas and not infrequently with injuries of the intestine.

It is difficult to believe that any gynecologist of that day could have been proud of the accomplishments in the field of surgery, and yet operative intervention was fully justified, because it was thus possible to salvage about a quarter of the patients who otherwise would be consigned to death by the palliative route. There was no other choice, indeed, until the introduction of radium. The earliest application of this substance was as a palliative for cancers which had been rejected as inoperable by the surgeon. It soon established itself as a definitely valuable palliative, superior to the cauterization or the acetone methods of palliation previously employed. There was often a striking retarding effect on the disease, and occasionally even a cure. It is also true that in the early days of radium therapy distressing injury was often inflicted by the radium itself. While the developments in technic which have occurred since then have greatly decreased these side effects of radiotherapy, they have not by any means eliminated them entirely, as attested by numerous reports in even the most recent literature.

It is small wonder that the early radium enthusiasts soon began to extend its use to the less advanced and less hopeless group of cases; those which might surgically be considered of borderline type. The palliative results were correspondingly better, with a more generous sprinkling of apparent cures in the borderline group, so that it was inevitable that before long even the early cases, those in which surgical intervention could be performed with a reasonably good chance for cure, were treated by radium alone.

With the passage of years it became apparent that radium could cure approximately the same proportion of patients as could even the most radical surgical procedure with almost no immediate mortality and with a lesser incidence of serious post-therapeutic complications. These facts were ample justification for the selection of radiotherapy as the method of choice in the treatment of cancer of the cervix, and this plan was for many years the prevailing one in almost all clinics. One did not need to be a radium enthusiast to concede the wisdom of such a plan under the existing circumstance. On the other hand, even if one conceded the preponderant advantages of radium therapy one could not criticize an occasional departure from the general plan. In a good many clinics, including this one, an occasional patient with an early form of cancer was subjected to radical operative intervention with no radiotherapy at all, this presupposing that the patient was in good condition for the operation and that the surgeon was thoroughly trained in the technic of the radical procedure. Throughout this whole period of ascendancy of radiologic therapy a few surgeons, notably Victor Bonney and Emil Ries, steadfastly clung to radical operative procedures as the method of choice.

with ultimate results comparing favorably with those obtained by radium therapy but still handicapped by a not inconsiderable primary mortality and morbidity.

In other words, the primary surgical era in the treatment of cancer of the cervix had given way to the radiologic phase. Gynecologists now appear to be passing into a third era, one of combined surgical and radiologic attack on the more favorable groups of cancers. Those of more advanced type, corresponding to stages 3 and 4 of the League of Nations' Classification, and most of those of stage 2, still constitute the exclusive domain of radiotherapy.

The rationale of this new trend is apparent when one considers that even after the most thorough application of radium and roentgen therapy, microscopic examination of follow-up biopsies shows residual carcinoma in a not inconsiderable proportion, often in clearly viable form. From such residues later recurrences may be expected, with increasing hazard of wider and wider dissemination through the lymphatics. Moreover, in a certain proportion of these patients the cancer appears to be resistant to radium therapy, this not being always explainable by the histologic cell type.

Many gynecologists and radiologists now consider that radical operative procedures should in selected cases follow radiotherapy, although there is still considerable variation in the details of the plan. Some employ only radium, others use roentgen therapy also, some preferring the roentgen application before radium, some after. It would lead too far afield to discuss the details of technic and dosage of these agents in the various clinics of the country and to compare the salvage rates reported by them, especially as it is still too early to reach any clear conclusion as to the most effective plan.

In the small minority of patients in whom hysterectomy is chosen, there is little difference of opinion as to the advantage of preliminary radiation. The two chief advantages are (1) the sterilizing effects of such preliminary therapy, thus greatly lessening the hazard of peritonitis, which has always been a bugbear in these radical procedures, and (2) the devitalization and fibrous entrapment of cancer cells, lessening the hazard of dissemination.

However, it should again be emphasized that the proportion of cases in which radical surgical intervention is considered justifiable is indeed small, and in many excellent clinics there are almost no exceptions to the radiotherapeutic plan for cervical carcinoma.

Just as there have been differences in opinion as to what constitutes the ideal plan of preliminary radiotherapy, so there have been differences in opinion and practice as to the scope of the radical procedure which should then be performed. With most gynecologists this differs from the ordinary panhysterectomy only in the removal of a large cuff of vaginal mucosa and as large a section as possible of the parametrium, through which the cancer cells drift outward to the pelvic glands. It does not, in most hands, include the formidable procedure of dissecting out the pelvic lymph glands, as was done in the original Wertheim type of operation. In my opinion there can be no question as to the value of removing a large section of the upper part of the vagina in view of the frequency of recurrence in this region. This recurrence usually represents only a persistence of cancer nests beneath a normal vaginal mucosa, as I have repeatedly seen in the laboratory study of such tissues.

There is still some conflict of opinion as to whether formidable glandular dissections are of sufficient advantage to the patient to justify the increased hazard of such procedures. Bonney, Meigs, Taussig and others have reported at least an encouraging number of cures after removal or radiation of involved glands. It is a well known fact that both the parametrial infiltration and the glandular enlargement seen with cancer is in a large proportion of cases of septic inflammatory type and not metastatic, so that meticulous histologic studies are necessary to validate conclusions as to the greater effectiveness of the more radical procedures.

Meigs [23] especially has recently adopted the extremely radical operation with extensive dissection of glands in a selected group of cases. Since most of the older master surgeons had gone through this phase, with final discouragement and resort to the safer radiotherapeutic plans, this reversion to surgical measures would seem indefensible except for the undeniable fact, as Meigs has emphasized, that the primary hazards of such extensive procedures have been greatly lessened by such surgical advances as transfusion, sulfonamide drugs and penicillin, none of which were formerly available to the surgeon. The results of the experiment which Meigs is carrying out, as he himself terms it, have already shown that this extensive operative procedure can be done with a primary mortality far less than was formerly noted, in fact without any deaths in the first 100 cases. However, the technical difficulties are the same for corresponding groups of cases, and the same types of complication still arise, as shown by the high incidence of ureteral injuries and fistulas in the first series of cases reported by Meigs, though the difficulties in this respect were apparently overcome in the second series.

As for the final results, it is as yet too early to evaluate them. The experiment is a laudable one, and the final result will be of general interest. I suspect, however, that most of those old enough to remember the earlier phase of extensive cancer surgery would for the present prefer to stand on the sidelines and watch this noble experiment rather than to take part in it themselves. Those who favor extremely radical operative procedures with complete dissection of the glands point to the extensive dissections of axillary glands performed by the general surgeon for cancer of the breast, but I do not think that any of these general surgeons is especially enthusiastic about the final results in cases of extensive axillary involvement. If the extirpation of the pelvic glands ensured the recovery of the patient it would be incumbent on all surgeons to follow this plan in otherwise operable cases, in spite of the magnitude of the operation and its definite hazard. But the glands do not constitute a sharp barrier to the disease, and it is highly probable that when they are extensively involved the cancer cells have penetrated beyond them into other lymphatic channels.

Finally, it should again be emphasized that what has been said as to the inclusion of various degrees of radical surgery as an important part of the treatment of cervical cancer applies, after all, to only a decidedly small proportion of all the cases. It pertains especially to the stage 1 cases, which make up not much more than 10 per cent, and to perhaps a few of the stage 2 group, together constituting not over 20 per cent of all cases seen. For the great majority of all cases, therefore, radiotherapy still remains about the only choice. It is not certain that even in the stage 1 cases the combined plan will give results better than radiotherapy alone. For example, in a recent study by Jones and Jones[24] a comparison was made of the results of panhysterectomy in 36 cases of early carcinoma, even including 5 of so-called preinvasive type, with those in 704 unselected cases of all stages treated by radiation. In the former group the five year cure rate was 41.6 per cent, in the latter 57 per cent. It is only fair to say that the operative procedure carried out in the surgical group was the so-called modified Wertheim operation, which did not include dissection of the glands but did include excision of as much parametrium and vaginal mucosa as possible. On the other hand, the cases were all of stage 1, and the results should therefore be properly compared with those of irradiation in the corresponding group. When one remembers that in this group figures as high as 80 per cent of cures have been reported, the superiority of radiation would seem apparent.

---

[23] Meigs, J. V.: Am. J. Obst. & Gynec. 49: 542, 1945.

An important point of discussion now revolves about the role of involvement of the pelvic gland in influencing one's choice of a method of treatment. Unfortunately the occurrence or extent of this complicating factor cannot be accurately determined preoperatively. The fact that it is seen in a large proportion of Meigs' cases, all of stage 1 or stage 2, is an indication that it is always to be reckoned with even in clinically early cases. This observation is difficult to reconcile with the good results obtained in this group by radiation alone, since it appears to be conceded that radiotherapy has little effectiveness in eradicating glandular metastases. The good results in grade 1 cancer are equally hard to reconcile with Martzloff's[25] conclusion that not a single patient in his large series of cases in which parametrial and gland involvement had been found survived beyond five years, even though the operations were radical and were performed by expert gynecologists.

The problem presented by pelvic glandular involvement has been approached in various ways, viz. (1) radiation, with at least questionable effect, and (2) wide dissection of the pelvic glands without hysterectomy, depending on radiation to take care of the uterine lesion. While good results were reported by Taussig[26] with this method, it has not met with any wide acceptance, probably because of increasing recognition that residual cancer in the uterus is common and that hysterectomy should be a part of any radical operation for cervical cancer.[3] Attention has already been called to the fact that Bonney[27] and a few other surgeons have consistently favored extremely radical operative intervention, both before and since the advent of radium therapy. While the end results in Bonney's five year cures compared favorably with those of radiotherapy, the primary mortality of 14 per cent, later 9.3 per cent, discouraged most gynecologists from the operative plan, once such an alternative as radium became available.

THE COMBINED PLAN OF TREATMENT

One of the earliest champions of the combined plan of treatment was Lynch,[28] whose pioneer work in this respect has not been sufficiently appreciated. His five year cure rate with extremely radical operative intervention was 85.5 per cent in stage 1 and 53 per cent in stage 2, but in the latter the operative mortality was decidedly high, 23.5 per cent. Some of the cases in both groups received preoperative radiation, some did not.

The comparative statistical studies of end results made in numerous clinics throughout the world have achieved at least some measure of standardization through the adoption of the various clinical classifications which have been devised. None of them, perhaps, is altogether ideal. The one most widely employed, that of the League of Nations Health Committee, has the rather serious disadvantage of giving its stage 1 too large a scope, especially in these days of intensive search for extremely early and even preinvasive lesions. The latter make up such a tiny, almost infinitesimal proportion of all cases that they have little bearing on the general statistical problem, and yet there is still uncertainty and difference in opinion as to the best plan of treatment, some preferring wide local incision, some radiotherapy, some amputation of the cervix, some total hysterectomy and some expectant treatment with close follow-up. By any method the results should be almost perfect if the lesion is really noninvasive, and this ready curability would seem to justify its segregation into a separate if small group or subgroup.

Again, there is wide difference in results between stage 1 cases in which the lesion is not over 1 cm. in diameter and those in which the entire cervix is involved, though the two extremes are included in this group. In the former there is seldom any vaginal or parametrial infiltration; with the latter it is common, though it may not be expected. In this respect the Schmitz classification has a definite advantage, for it takes cognizance of these subdivisions in its stages 1 and 2. Cancers in the more advanced groups are practically all treated by radiation, but with the cases in stage 1, especially, various methods of management are now being used which often involve combinations of irradiation and surgical measures, so that efforts at sharper subdivision would seem advisable. They would even serve an educational purpose, emphasizing the increasing frequency of lesions in a far earlier stage than those conceived of when the classification plans were evolved. Though there is no novelty in the suggestion, a subdivision of stage 1 of the present League of Nations system would seem advisable. Three such subgroups suggest themselves. Stage 1 (*a*) might include the still infrequent but highly curable preinvasive cases; stage 1 (*b*) those in which the cervical lesion is not over 1 cm. in diameter; stage 1 (*c*) those in which the lesion is limited to the cervix but is larger than 1 cm. in diameter. Stage 2 would include those in which large areas of the cervix or the whole cervix is involved, with moderate vaginal and parametrial infiltration.

Stages 3 and 4, including cases largely unfavorable and definitely nonsurgical, could remain as at present described under the League of Nations' Classification. The criterion of pelvic lymph node involvement is a decidedly unreliable one to employ for clinical classification, important though it is in influencing the outcome. Such involvement can be determined clinically in only a fraction of the cases in which it is present. While it can be almost assumed in the advanced case, it may occur even in the clinically early one, as shown in the operative data of Bonney, Meigs and others. On the other hand vaginal and parametrial infiltration is readily demonstrable by vaginal and rectal examination. It therefore furnishes a more useful index for the clinical stage, though such infiltration does not by any means indicate malignant extension, being often of septic inflammatory nature.

[28] Lynch, F. W.: Am. J. Obst. & Gynec. **22**: 550, 1931.

The treatment of corporeal carcinoma has always been somewhat simpler than that of cervical cancer, not merely because of the more favorable results obtained but because there has usually been a reasonable degree of uniformity of thought as regards the general principles if not the details of treatment plans. To revert again to the preradiation era, the surgical plan was then the universal one, and with much justification, because of the slower extension of the lesion, the far greater ease and safety of the operations indicated in such cases, and the reasonably high rate of cure. In the earlier cases five year survival rates as high as 70 per cent were reported by some, though the reports of others, like Norris and Vogt,[29] were much less favorable. Moreover, the operability rate was high, the only cases excluded being those far advanced and those in which any form of operative intervention appeared contraindicated because of such factors as advanced age, extreme obesity, general debility and serious systemic disease.

The advent of radium did not at first make any serious impression on this prevalent tendency to use surgical methods in the treatment of endometrial carcinoma, although later, chiefly because of the good results reported by Heyman,[30] there was a limited and short-lived resort to radiotherapy alone. With this form of uterine cancer even more than with the cervical variety a stage of combined surgical and radiotherapeutic management now seems to have established itself as superior to that of surgical intervention alone or radiotherapy alone.

Even after intrauterine radium therapy which is considered fully adequate by modern standards viable cancer is revealed in a large proportion, something like 50 per cent, of the subsequently removed uteri. The proportion would probably be higher if the microscopic examinations were more painstaking. The difficulties of precise intracavitary therapy are well recognized, and though various types of applicators have been devised to lessen this serious disadvantage the problem still remains. There are now, to my knowledge, no dissenters from the view that panhysterectomy is the most important part of the treatment of corporeal carcinoma. Somewhat less unanimous, but accepted by most of those of largest experience, is the conviction that the hazard of operative treatment is definitely lessened and the final results improved by radiotherapy as a preliminary to operation. The devitalization of the cancer cells, their imprisonment by the fibrotic reaction produced by radium or roentgen radiation, the sterilization of the cancer lesion and the consequent lessening of the operative hazard, all these are advantages which appeal to reason and which are apparently justifying themselves by the improvement in results following such a plan. There are of course certain disadvantages, such as the delay of six to eight weeks commonly prescribed as the ideal interval between radiotherapy and operative procedures.

Moreover, there is still wide variation as to the form of radiotherapy to be employed. Scheffey[31] and his group are warm advocates of radium therapy alone and have reported the astonishingly high five year cure of 90 per cent in a very small group of grade 1 cases. Miller and Henderson,[32] however, prefer roentgen therapy as the preliminary to operation, while in still other clinics both forms of treatment are employed. Without an exhaustive analysis of individual results, the evidence now available indicates that the best results are obtainable by the application of the general therapeutic principle of panhysterectomy and bilateral oophorectomy preceded by radiotherapy. Time will determine just what radiotherapeutic plan is the most effective and most practical. To say that there should never be any departure from this general plan would be absurd, just as it would be to assume that the general principle which has been enumerated is the final word on the subject, because it certainly is not.

POPULAR EDUCATION

The most important of all weapons against cancer, in the present state of medical knowledge, is the one which I shall treat most briefly because it is so self evident and because it has been urged so long, so widely and so forcefully that it seems almost banal to elaborate on it. All the statistics that have ever been compiled on the results of cancer treatment have shown again and again that the patients who obtain proper treatment have a fine chance for cure, those coming late comparatively little. If all cases were of group 1, cancer of the cervix would not be the dreadful disease that it is. The moral is plain enough, but it has not been easy to impress it on the public mind.

The patient is an essential part of medical treatment, and unless the patient makes some sort of contact with the physician the latter cannot give her the benefit of either his diagnostic or his therapeutic resources. Herein lies the great opportunity for popular education, and such organizations as the American Cancer Society have been rendering valiant service in this field. Periodic examinations and cancer detection clinics are a part of this educational crusade. The results achieved by such clinics are not to be measured by the comparatively small number of unsuspected cancers thus far revealed, but rather by the fact that they become foci for an ever widening interest among women in their own protection against one of their worst enemies. Every woman under the surveillance of such a clinic is likely to spread the lifesaving gospel among her friends. If every woman could have a competent gynecologic examination every six months, with proper treatment if necessary, the mortality due to cancer would drop like the proverbial shot.

Nor can the whole burden be placed on the woman, since the members of the medical profession are far from clear of responsibility for serious delays in the diagnosis of cancer. Ignorance is seldom the reason for delay, as there is not a physician in the world who does not know that early diagnosis means an increased chance for cure. More often it is a curious lack of personal responsibility for the patient's welfare, a mental apathy or lack of conscientiousness which leads the physician to drift along rather than to buckle down intensively to the solution of the problem. Volumes could be written on the education of both the laity and the medical profession, but this is scarcely the place to do more than underscore the outstanding importance of early diagnosis and treatment. Until much more decisive methods of cure are available, the educational campaign offers itself as the wide open avenue for lessening the mortality due to cancer.

THE ANTIHISTAMINIC DRUGS

GEORGE L. WALDBOTT, M.D.
Detroit

Any medicament, no matter how valuable, may do great harm if it is employed indiscriminately. The fame of the new antihistaminic drugs has become so widespread, indeed, that they are often prescribed merely to satisfy the patient's curiosity. A critical inventory of their value is therefore indicated.

When an antigen to which a patient is sensitive enters his system, certain antibodies called "reagins" are formed, which are responsible for the allergic wheal. Simultaneously a protective antibody may originate, which is thermostabile (Loveless[1]) and presumably accounts for the improvement of the disease. The combined action of antigen and specific reagin in the bloodstream or in the tissues releases histamine and histamine-like substances which dilate capillary blood vessels and induce smooth muscle spasm, especially bronchospasm. Thus through the action of histamine the allergic wheal is formed—on the skin in urticaria; in the nose and sinuses in hay fever; in the mucous membranes of the bronchial tree in asthma, and in certain cerebral structures in migraine. Secondary infection may supervene, as in chronic sinusitis, bronchial asthma and allergic eczema.

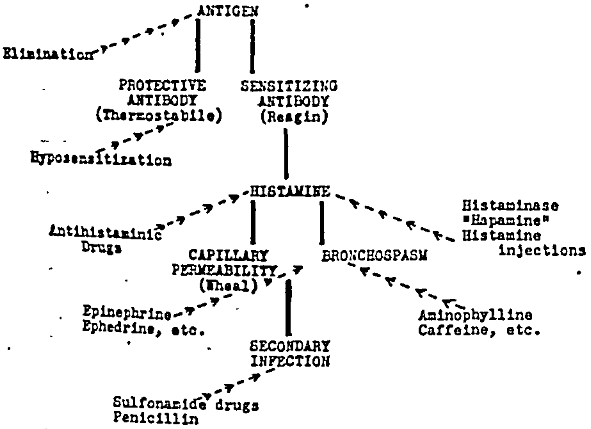

Fig. 1.—Interference of antihistaminic agents with phases in the development of allergic diseases.

The well known remedies for allergic diseases are designed to interfere with one or another of these phases in the development of the disease (fig. 1). For instance, one may attempt to eliminate the antigen from the patient's surroundings and from the diet. One may endeavor to produce the protective antibody by hyposensitization. Epinephrine and ephedrine contract the capillaries, thus they counteract the allergic wheal. They also relieve the spasm of smooth muscle. The remarkable effect of aminophylline in asthma is due mainly to relaxation of bronchial musculature.

Attempts have been made to counteract the effect of histamine (Feinberg[2]) in the chain of events leading to allergic manifestations. The enzyme histaminase (available commercially as "torantil"), which destroys histamine in vitro, has not proved to be of clinical value. Efforts toward building up an immune substance against histamine by injecting increasing doses of either histamine itself, or of histamine linked with protein (a product called "hapamine") have also met with little success.

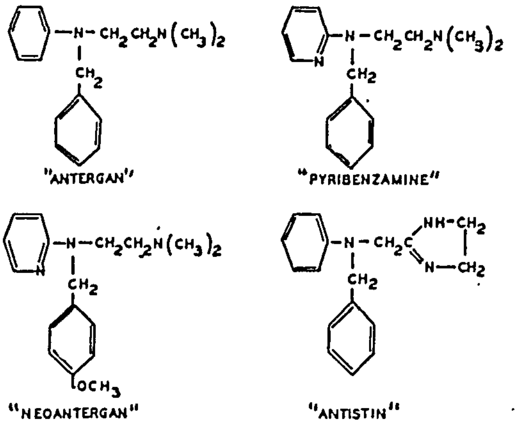

Fig. 2.—Ethylenediamine derivatives.

In 1933 Fourneau and Bovet[2] first demonstrated that certain phenolic ethers counteract the action of histamine in vitro and in vivo. Many such compounds have been, and are still being, synthesized both in Europe and in this country. Many had to be discarded because of their toxicity. The most promising ones[2a] are N-phenyl-N-benzyl-aminomethyl-imidazolin ("antistin") and N-p-methoxybenzyl-N-dimethylaminoethyl α aminopyridine ("neoantergan"), which were developed in Europe, and tripelennamine hydrochloride ("pyribenzamine hydrochloride") and diphenhydramine hydrochloride ("benadryl hydrochloride"), which originated in this country (figs. 2 and 3).[3]

These drugs specifically counteract most of the physiologic effect of histamine: in animals they diminish capillary permeability resulting from histamine, thus they counteract the histamine wheal. They raise blood pressure, which had been lowered by histamine. They prevent contraction, by histamine, of intestinal and uterine strips from guinea pigs, both when the drug is added to the fluid in which the strip is suspended and when it is administered to the intact animal before the experiment.

These drugs inhibit secretion induced by histamine in the lacrimal and salivary glands and the mucous glands of the bronchial tree. This is a clinically significant point, because excessive mucous secretion is a cardinal feature both in allergic rhinitis and in

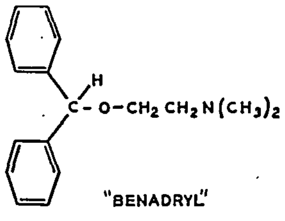

Fig. 3.—Ether derivative.

Read in the General Scientific Meetings at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 9, 1947.

[1] Loveless, M. H.: Immunologic Studies of Pollinosis: I. The Presence of Two Antibodies Related to the Same Pollen-Antigen in the Serum of Treated Hay-Fever Patients, J. Immunol. **38:** 25-50 (Jan.) 1940.

[2] For a complete bibliography on the subject, I wish to refer to the article of Feinberg, S. M.: Histamine and Antihistamine Drugs, J. A. M. A. **132:** 703-714 (Nov. 23) 1946.

[2a] "Antistin" and "pyribenzamine hydrochloride" are manufactured by Ciba Pharmaceutical Products, Inc.; "neoantergan" by Merck & Co., Inc., and "benadryl hydrochloride" by Parke, Davis & Company.

[3] Two widely publicized drugs, 1-dibutylaminomethyl-5,6,7-trihydroxy isobenzofuran-(3)-one ("anthallan") and ethylene disulfonate ("allergosil"), have no connection with these drugs and have been of no value in my experience.

asthmatic attacks. These drugs produce local anesthesia when injected as well as when applied topically. They prevent death from a lethal injection of histamine in experimental animals. Friedlander and Feinberg[4] observed that in this action "neoantergan" was most efficacious, followed by "pyribenzamine," "antergan" and "benadryl." In their effectiveness in protecting against anaphylactic shock, however, no individual variation could be observed. On the other hand, "benadryl" was found to be more effective than the other drugs in preventing intestinal spasm in guinea pigs (Sherrod, Loew and Schloemer[5]). From all this it appears that these drugs somehow counteract the pharmacologic properties of histamine. They do not chemically neutralize histamine nor do they prevent its production in the body; they are believed to compete with histamine in its affinity for the cells.

Clinical evaluation of any drug in allergic diseases is fraught with great difficulties: Allergic manifestations are frequently self limited, especially acute reactions such as those encountered from penicillin therapy. Even in such chronic conditions as perennial rhinitis and chronic asthma, spontaneous improvement may take place at any time because of sudden disappearance of certain inhaled or ingested antigens from the patient's environment and because of the likelihood of spontaneous desensitization to certain antigens, especially foods. Psychogenic influences play an important part; the administration of a capsule or injection of any drug may bring about relief, especially if the drug has been widely popularized by the members of the profession and by the lay press.

Clinically, the effect of the antihistaminic drugs reflects their powerful antagonism to histamine, which has been observed experimentally. Two actions stand out, ability to inhibit whealing and to dry up mucous secretion. Urticaria (table 1) therefore responds most dramatically: in both the allergic type and the serum sickness type of urticaria[6] complete subsidence of symptoms takes place in about 85 to 95 per cent of patients within twenty minutes after the ingestion of 50 to 100 mg. of the drug. The symptoms recur after four to six hours. The action of the drugs, therefore, is entirely palliative. In all other allergic diseases in which whealing and edema are prominent the benefit would probably be equally as striking, were it not for the fact that some degree of secondary infection usually becomes rapidly superimposed on the primary allergic changes. In hay fever, for instance, the antihistaminic drugs are most beneficial during the early part of the season when the sinuses and the nasal mucosa secrete clear, watery fluid and when there is no evidence of secondary infection. Waterlogged mucous membranes and nasal polyps shrink visibly within thirty minutes after ingestion of the drug. This is also true in perennial allergic nasal and sinus disease in the absence of suppurative changes. The drugs are highly effective in incipient asthma, both in the infantile type characterized by edema in the lungs as well as in the pertussis-like cough of allergic bronchitis, which so often inaugurates asthma. If the disease has progressed to the stage at which the characteristic thick, tenacious expectoration is present, there is considerably less, if any, benefit from the oral administration of the drugs. Given intravenously, however, severe attacks of asthma have been controlled temporarily by the antihistaminic drugs when aminophylline and epinephrine have failed. In allergic shock due to the accidental intravenous injections of antigens[7] or in shock from ingestion or inhalation of antigens to which the patients are extremely sensitive the action of the drugs is most impressive. They should be held readily available for intravenous administration in doses of 10 to 50 mg. for such emergencies.

TABLE 1.—*Estimated Efficacy of the Antihistaminic Drugs*

	Per Cent of Efficacy *
Urticaria	85 to 95
Hay fever	70 to 80
Vasomotor rhinitis	60 to 70
Asthma: Oral	40 to 50
Intravenous	65 to 75
Pruritus of eczema and contact dermatitis	30 to 40
Migraine	25 to 35
Gastrointestinal allergy	Doubtful

* Based on own data, those of Dr. Carl Arbesman, Buffalo, and the review of Dr. S. M. Feinberg.[2]

TABLE 2.—*Untoward Effects*

In Animals	In Men			
		Toxicity		
Toxic Dose: About 20 Mg. per Kg.	Side Effect *	Acute (2,000 Mg. in 48 Hrs.)	Chronic	Allergic Symptoms
Excitation Convulsions Lethargy Nasal and intestinal hemorrhages	Dizziness and sleepiness in 20 to 50% Dryness in mouth Headaches Nausea, vomiting Muscular twitching Paresthesia *Dilated pupils*	Only 1 case reported: Confused Lethargic Disoriented Shock	Granulocytopenia (?)	Asthma Cough Dermatitis † Urticaria †

* More pronounced with "benadryl" and "antistin," less with "pyribenzamine" and "neoantergan."
† Extremely infrequent.

The pruritus of atopic eczema and of contact dermatitis of the poison ivy type is effectively controlled, especially if it is associated with localized edema as encountered during acute exacerbations. There is little benefit in these conditions when secondary infection complicates the situation. The anesthetic properties of the drugs may be utilized by topical applications through compresses and ointments. In allergic headaches it is difficult to evaluate their efficacy. Experimentally, prophylactic injections of "benadryl" prevent headaches induced by histamine (Goodman and Conrad[8]). Similarly, histamine cephalalgia appears to respond to the drugs, especially to their intravenous administration. However, in true allergic migraine and in headaches associated with allergic sinus disease their effect is doubtful. In a few instances of gastrointestinal allergy which I encountered, improvement ensued. In allergic conjunctivitis topical application of a 0.5 per cent solution of "antistin" (Bourquin[9]) promptly controls photophobia, itching and lacrimation. The other drugs may be employed in the same manner.

Oral doses of 50 to 100 mg. are also desirable. Erythema multiforme[10] and allergic purpura have also been named as being greatly benefited by them.

Among nonallergic diseases the antihistaminic drugs are reported to control and prevent irradiation sickness, which is believed to be brought on by the release of histamine (Lofstrom and Nurnberger[11]). Unfortunately, attempts to relieve gastric ulcer through the inhibition of gastric secretion by the drugs have failed so far.

Twenty to fifty per cent of all patients taking antihistaminic drugs experience side effects such as drowsiness and dizziness associated with a peculiar feeling of floating and being suspended (table 2). Headaches, nausea, dryness in the throat and muscular twitching are other side effects. These manifestations are noted more frequently with "benadryl" and "antistin" than with "pyribenzamine" and "neoantergan." They may appear with the first doses and be absent later, or vice versa. In some instances the sedative effect of the drugs contributes to the patient's subjective improvement; in others these manifestations constitute extremely serious, although only temporary, disturbances.[12] Prolonged administration of the drugs for weeks and months has thus far not resulted in any demonstrable organic damage either in human beings or in animals. So far there is no indication of a cumulative action or of addiction to the drugs. However, several patients have been encountered in whom there developed allergic manifestations from the antihistaminic drugs; namely, dry allergic cough, urticaria or dermatitis. Aggravation of existing asthmatic wheezing is occasionally noted. With the increased use of these drugs physicians will have to reckon with the development of sensitivity to them.

From all this it is evident that the antihistamine drugs deserve a definite place in the management of allergic diseases equal, and in some instances superior, to that of such established agents as epinephrine, aminophylline and ephedrine. Like these, they are purely palliative, they have unpleasant side effects and they in no way affect the course of the disease. They can be conveniently combined with other measures. Because of their specific action against histamine, they may serve as a differential diagnostic medium both clinically and experimentally.

A warning should be sounded against extravagant claims by overenthusiastic clinicians and patients, who are sometimes inclined to exaggerate the benefits obtained and to use the drugs indiscriminately. It is unsound to administer any drug to allergic patients on a routine basis rather than when the particular need arises. Patients should be warned against driving a car or operating a moving machine while taking these drugs, because accidents due to their soporific by-effect have already been reported.[13] It should be emphasized that there is a possibility of development of sensitization to these drugs. Moreover, it has not yet been determined whether or not they interfere with treatment directed toward development of specific immune substances. Undoubtedly the greatest significance in their development is the new principle which has instigated their trial and which will lead to further understanding of the mechanism of allergic diseases and perhaps to further therapeutic success.

ADDENDUM

Halpern of Paris, France, recently reported on a new series of compounds,[14] the thiodiphenylamine derivatives, which were more effective and less toxic in animal experiments than any reported previously. Two compounds, 3015 RP (dimethyl-aminoethyl-thiodiphenylamine) and 3277 RP (dimethyl-amino-2-propyl-1-thiodiphenylamine) were found to be particularly potent.

DIABETES IN A NEW ENGLAND TOWN

A Study of 3,516 Persons in Oxford, Mass.

HUGH L. C. WILKERSON, M.D.
Surgeon, U. S. Public Health Service
and
LEO P. KRALL, M.D.
Senior Assistant Surgeon, U. S. Public Health Service
Boston

In a community study of diabetes mellitus, 3,516 of the 4,983 inhabitants of Oxford, Mass., were tested for the disease. Diabetes mellitus is increasing in the United States, but an accurate determination of the prevalence of the disease among the general population is needed.

Estimates of the prevalence of diabetes vary considerably. With figures based on the count of living diabetic persons obtained by the National Health Survey[1] in 1935-1936, with appropriate adjustment for underenumeration, the United States Public Health Service estimated that the number of diabetic persons in the continental United States in 1937 was 660,000, approximately 0.37 per cent of the population. It must be recognized that this estimate is based on prevalence data supplied by family informants, usually housewives, for all members of their households.

Later studies in this field have suggested higher prevalence estimates. Thus Marks[2] recently estimated that the number of living diabetic persons in the United States was 675,000, while Joslin[3] and others believe that there are 1 million living diabetic persons in the country.

De Porte[4] reported that a survey in a rural county of New York in 1927-1928 revealed 154 cases of dia-

---

Because of lack of space, this article is abbreviated in THE JOURNAL by omission of the illustration and of tables 3 and 5. The complete article will appear in the author's reprints.

Appreciation is expressed for the cooperation in this work by the four practicing physicians of Oxford, Mass. (Drs. Robert Fletcher, Herbert Hale, Joseph Lundy and Walter Schur); the Massachusetts State Medical Society, and the Worcester District Medical Society.

Acknowledgment is made of the assistance in the survey of Malcolm Ford, Surgeon, U. S. Public Health Service; Nell McKeever, Health Educator; Barbara Dormin and Teresa Hayes, Public Health nurses; Barbara Glenn, statistician; the technicians and clerical workers of the Diabetes field staff, and Constance Sellman, Director of the laboratory of the New England Deaconess Hospital. Also, the study would not have been possible without the wholehearted aid of the Selectmen, school officials and citizens of Oxford, Mass.

betes in a surveyed group of approximately 18,000 persons (a rate of 0.9 per cent). In a house to house canvass of 34,663 persons in Philadelphia,[5] 357 persons, about 1 per cent of the group, were diabetic.

Recent investigations based on physical examinations, which included laboratory analysis of specimens of blood and urine, have suggested that the prevalence of diabetes may be much higher than that indicated by surveys which included only known or recognized cases. In an industrial survey (Gates [6]) 109 persons believed most likely to have diabetes among a total of 1,800 employees were selected for dextrose tolerance tests. There were found to be at least 20 diabetic persons among the 1,800 persons, in 12 of whom the disease had not been previously diagnosed.

The prevalence of diabetes in two different groups of Massachusetts selective service registrants has been reported by Blotner and Hyde.[7] In the two groups a total of 114,738 men were examined, and 997 were found to have diabetes. Of these, approximately three-fourths had no knowledge of their condition. The occurrence of diabetes among a group of nearly 150,000 National Youth Administration [8] employees between 16 and 24 years of age who were examined by urinalysis was 1.2 per 1,000, a rate twice as high as that found for persons in the corresponding age group in the National Health Survey.

It is probable that the aging of the population as well as the lengthening of the diabetic person's life span will increase the total number of those with diabetes in the future. Spiegelman and Marks [9] have pointed out that by 1985, according to present indications, the total population of the nation will be at a maximum and one may expect an increase of 74 per cent in the diabetic population, while the general population will have increased by only 22 per cent.

While the population ages, the future trend in morbidity and mortality due to diabetes may not be unalterable. Scott [10] has emphasized that when knowledge of the methods of treatment employed in the best hospitals becomes universal, "diabetics will no longer die of diabetes. They will live long enough to die of one of the so-called 'natural causes' of death." Joslin [11] has stated that "one almost might say that a death from diabetes is no longer allowable."

Both experimental and clinical experience demonstrate the value of early diagnosis to make possible early treatment of diabetes. The assurance of benefits from a case-finding study rests on a reliable body of scientific knowledge. A theory generally accepted today is that the insulin insufficiency of diabetes results from a decreased functional capacity of the islands of Langerhans in the pancreas.[12] There is evidence from work with experimental animals that the islet cells of the pancreas have a capacity for regeneration and that early pathologic changes in diabetes are reversible. Reference is made to the work of Copp and Barclay;[13] Lukens and Dohan,[14] and Haist and Best [15] for experiments which bear out this hypothesis.

It is understood that human diabetes may not be entirely comparable to the diabetes found in experimental animals, but it is important that prevention should be attempted in susceptible human subjects.

It would seem clear that the period of reversibility which has been demonstrated is of utmost importance in the prevention of the disease. According to Joslin and associates,[16] the prevention of diabetes in man will "depend upon a knowledge of the duration and occurrence of this period of reversibility and on our ability to diagnose the disease during this period." John [17] has observed that early diagnosis of diabetes in the Army has meant in general a better outlook and a milder routine for the diabetic person.

Warren and Root [18] have interpreted the pathologic condition of the pancreas in diabetes as a constantly changing condition—island cells being gradually destroyed by long-continued action of an injurious agent (or possibly excessive functional activity); new cells being formed subsequently and destroyed by the toxic agent. This process goes on for some time, bu eventually the destructive process wears down th regenerative powers of the pancreas; thus the unfavor able course of the disease is explained. Warren has expressed the belief that this dynamic concep "explains the improvement of tolerance, fortunatel now occasionally encountered, as the regenerativ power of the pancreas outstrips the destruction of th pancreatic tissue by the injurious agent. This lead to the hope that in young persons with more resilien tissues proper treatment may remove the cause injury and favor the more or less complete restoratio of the damaged islands."

This knowledge of the reversibility of patholog changes in the pancreas represents an important contr bution to the physician's limited understanding of th causes and prevention of diabetes. Early discovery cases of diabetes may be considered a form of pr ventive medicine, because early diagnosis reduces th liability to serious progression and to the onset dangerous complications. To quote from Haist an Best,[20] "We are anxious to stimulate interest in th possibility of preventing diabetes, since from the poin of view of public health this is the most importan aspect of the diabetic problem."

For better public health control of the disease ther must be a greater realization by the public and th members of the medical profession of the prevalence diabetes and the importance of early diagnosis.

In its first community study of diabetes, the Unite States Public Health Service has sought to demon strate the practicability of a case-finding study to

(*a*) determine the prevalence of diabetes in a typical American community; (*b*) evaluate the technics and methods of large scale diabetes diagnosis; (*c*) instill in the members of a community a realization of the need for periodic examinations for diabetes, and (*d*) discover early cases of diabetes so that, through prompt treatment by the family physician, further progression and complications may be avoided.

With these objectives in view, members of the United States Public Health Service tested 70.6 per cent of the 4,983 inhabitants in Oxford, Mass.

METHOD OF STUDY

Material and Method.—The site selected for the study was Oxford, Mass., located about 50 miles west of Boston. It is a typical New England town with 4,983 inhabitants. In age composition the population of the town closely parallels that of the country as a whole[21] as well as that covered by the National Health Survey (table 1). The people are mostly native born. Persons of French-Canadian descent compose about one third of the adult population, while many others are of old Yankee lineage, English or Scotch derivation. Some of the citizens are farmers, while many work in the local mills and still others commute to places of employment in Worcester, Webster and nearby communities.

Oxford is the birthplace of Clara Barton, founder of the American Red Cross, and is also the location of a summer camp for diabetic children. Oxford is the town referred to by Joslin[22] in a statement which presented one of the earliest conceptions of diabetes as a public health problem:

> . . . In a country town in New England . . . on its peaceful, elm-lined Main Street, there once stood three houses, side by side, as commodious and attractive as any in the village. In these three houses lived in succession 4 women and 3 men—heads of families—and of this number, all but one has subsequently succumbed to diabetes. . . .
>
> Although 6 of the 7 persons dwelling in these adjoining houses died from a single complaint, no one spoke of an epidemic. Contrast the activities of the local and state boards of health if these deaths had occurred from scarlet fever, typhoid fever or tuberculosis. Consider the measures which would have been adopted to discover the source of the outbreak and to prevent a recurrence. Because the disease was diabetes, and because the deaths occurred over a considerable interval of time, the fatalities passed unnoticed.

TABLE 1.—*Comparison of the Age Distribution of Oxford, Mass., with the Population of the United States and with the Population Canvassed in the National Health Survey*

	Per Cent in Each Age Group			
Age	Oxford Total	Oxford Group Tested	United States 1945[21]	National Health Survey[9]
Under 15	24.8	26.5	25.2	24.1
15 to 24	16.1	14.8	17.0	17.8
25 to 34	16.5	17.2	16.1	17.0
35 to 44	13.7	13.9	14.0	15.8
45 to 54	11.0	11.7	11.8	12.1
55 to 64	8.3	8.4	8.7	7.3
65 to 74	6.4	5.5	5.0	4.1
75 and over	3.2	2.0	2.2	1.6
Unknown ages	...	...	...	0.2
Median age	30.5	30.0	29.7	29.7

During the last ten years, according to local death records, 16 persons in this town have died of diabetes, 9 of them in their fifties or sixties. This number of deaths is consistent with the average diabetes death rate in Massachusetts.

TABLE 2.—*Population of Oxford, Mass., by Age and Sex in 1945; Number and per Cent of Population Tested for Diabetes in Oxford Survey by Age and Sex, 1946-1947*

	Oxford Population *			Oxford Residents Tested			% of Oxford Population Tested		
Age Interval	Total	M.	F.	Total	M.	F.	Total	M.	F.

45 to 54	550	275	275	411	196	215	74.7	71.3	78.2
55 to 64	412	216	196	295	146	149	71.6	67.6	76.0
65 to 74	320	158	162	192	86	106	60.0	54.4	65.4
75 and over	160	75	85	69	33	36	43.1	44.0	42.4
Unknown ages	1	1	..	2	2	..	....	....	....

* Age and sex distribution was tabulated from the 1945 Massachusetts State Census of Oxford.

The study in Oxford was initiated with the aid of the state and district medical societies, the state and local boards of health and the four local physicians. An attempt was made to determine the number of known cases and to discover the previously unrecognized cases. The excellent cooperation of the townspeople is evidenced by the fact that 70.6 per cent of them received the test, with coverage better than 65 per cent in every age group except the very young and those over 65 years (table 2).

The Public Health Service personnel assigned to the project included a physician trained in diabetes, a health educator, two public health nurses, a statistician, four technicians and a clerk-stenographer.

Two interview centers were established, one at the town hall and the other at the fire station. Appointments were timed so that specimens of urine and venous blood were obtained about an hour after the midday or evening meal. Capillary blood specimens were drawn from the fingertip or ear lobes of children, whereas most of the adults had venipunctures. The school children and service organizations were tested in groups.

Specimens of urine were tested immediately at a temporary laboratory in the town hall, while protein-free filtrates from the specimens of whole blood were made and promptly forwarded to the Boston laboratory of the Diabetes Demonstration Unit for final analysis.

The urine sugar was determined on each specimen by a standard Benedict's qualitative test, followed up when positive by a quantitative Benedict's test.

The blood sugar was determined in a 2 cc. specimen of venous blood according to the method of Folin and Wu.[23] In the case of a capillary specimen, a Folin-Malmros[24] micro sugar test was performed on a 0.1 cc. specimen. To verify the fidelity of the blood tests, frequent spot checks were performed in the laboratory of a large Boston hospital.

Diagnosis.—While the diagnostic criteria for diabetes mellitus adopted by different workers vary, it seemed practicable to adopt a single set of standards. On recommendation of an advisory committee of physicians from several clinics in Boston, a consistent one to one and one-half hour postprandial venous blood sugar of 170 mg. per hundred cubic centimeters or above or a capillary blood sugar of 200 mg. or more per hundred cubic centimeters plus glycosuria was considered to be presumptive laboratory evidence of diabetes.

For the group tested in Oxford, the routine was as follows:

1. The screening level for hyperglycemia was selected as 160 mg. per hundred cubic centimeters for venous blood and 190 mg. for capillary blood.
2. A person with no glycosuria and a blood sugar below screening level was notified by letter that the result of his test revealed no laboratory evidence of diabetes at the time.
3. On the initial laboratory test, if a person had any degree of glycosuria and/or if he had a blood sugar above screening level he was given a further test of urine and blood. If the results of the second test were above the diagnostic level, a diagnosis of diabetes was made. A negative second test following an initial borderline test was considered to be nondiabetic, and the person was notified accordingly.
4. A dextrose tolerance test was performed if the initial and recheck tests were not in accord, if both tests were borderline or if there was persistent hyperglycemia without glycosuria or vice versa.
5. If a person gave a history of previously known diabetes, blood and urine tests were performed to determine the patient's condition and the laboratory report was forwarded to the family physician. The family physician was consulted in order to confirm the diagnosis in every case of allegedly previously known diabetes.

In those cases in which dextrose tolerance tests were performed an overnight fasting reading was obtained for blood and urine, then the subject was given 100 Gm. of dextrose orally and specimens were obtained one, two and, when possible, three hours later. In a few instances, usually because of advanced age, the person was given 50 Gm. of dextrose with his regular meal, and then specimens of blood and urine were secured.

If a subject showed glycosuria in one or more of the specimens and a venous blood sugar level of 170 mg. per hundred cubic centimeters or above after the ingestion of dextrose, this condition was considered indicative of diabetes. While primary consideration was given to the height rather than to the duration of the curve, there was cognizance given to the opinions of eminent workers[25] that the duration of the curve is of great importance in the diagnosis of diabetes. The future progress of the patients will be followed in the few cases which might not be considered diabetic in some clinics.

If the person consistently demonstrated glycosuria and yet the blood sugar levels were within the normal range, a diagnosis of unclassified glycosuria was made. In cases of recurrent hyperglycemia without accompanying glycosuria a diagnosis of hyperglycemia without glycosuria was made.

During the course of the survey there were a few persons who refused blood tests but submitted specimens of urine, and without exception those with a trace or more of glycosuria agreed to further studies.

After the tests were completed each person was classified in one of the following ways:

1. Normal; no evidence of diabetes.
2. Known diabetes; previously diagnosed.
3. Newly discovered diabetes mellitus.
4. Unclassified glycosuria.
5. Hyperglycemia without glycosuria.

Whenever positive observations were confirmed and a tentative diagnosis was made, the patient was notified of an "abnormal condition" and advised to see his own family physician for any additional study or treatment indicated. The complete results of the survey were forwarded to the physician with an offer to perform any further tests he might wish in connection with diagnosis of the case.

RESULTS OF STUDY

Incidence of Diabetes.—Forty persons with prev ously diagnosed diabetes were found. One hundre and ninety-one other subjects with glycosuria, hype glycemia or both were retested. As a result, 30 pr viously undiagnosed cases of diabetes were found, pl 25 cases of unclassified glycosuria or hyperglycemi The other persons whose further tests showed no lal oratory evidence of diabetes were notified accordingl Those with diabetes and related positive observatior were referred to their family physicians, who wei also given a history and a detailed report of laborator studies.

A total of 39 dextrose tolerance tests were pe formed to check preliminary results. Seventeen of tl 30 new cases of diabetes were diagnosed with the ai of these tolerance tests. In 4 of the 17 cases a dia nosis was made with a modified type of test previous described. The patterns obtained in 13 standard de trose tolerance tests in cases diagnosed as diabetes a shown in the accompanying chart.

As might be expected, the majority of the cases wi both hyperglycemia and glycosuria on the first test we finally diagnosed as diabetes. See table 3 for results the screening process. Sixteen of the 25 persons this category were subsequently proved to have di betes, and their glycosuria and hyperglycemia on initi tests were on the average significantly higher than t levels observed for the 9 subjects ruled out of th group. However, on the first test, for those late termed diabetic, the degree of glycosuria ranged as lo as 0.3 per cent and the venous blood sugar as low a 162 mg. per hundred cubic centimeters.

The observation most commonly positive was glyco suria in the absence of hyperglycemia. This conditio was found in 123 initial tests, but in only 6 of thes cases was a diagnosis of diabetes thought justifiabl In these 6 cases the degree of glycosuria ranged fro 0.2 to 2.4 per cent. The average was 0.7 per cent compared to 0.4 per cent in those later proved non diabetic. Also, the capillary blood sugar level for thes 6 persons was relatively high, with an average o 165 mg. per hundred cubic centimeters as compare with 123 mg. for those with transient glycosuria.

In the interpretation of the significance of glycosuria the value of blood tests as a complement becomes apparent. There were 104 persons with glycosuria on the first test which did not recur on later tests; in 80 of these the level was 0.3 per cent or less. This condition was relatively common in school children and in several pregnant women, but no satisfactory explanation was found for its presence in the other adults. Lawrence[26] has expressed the belief that many of these irregular "alimentary" glycosurias are not negligible but rather a form of carbohydrate intolerance that may be a precursor of early diabetes.

---

[25] (*a*) Mosenthal, H. O.: Interpretation of Glucose Tolerance Tests, M. Clin. North America **31**: 299-312 (March) 1947. (*b*) Lawrence, R. D.: Symptomless Glycosurias: Differentiation by Sugar Tolerance Tests, ibid. **31**: 289-297 (March) 1947.

Tentatively 17 subjects were considered as having unclassified glycosuria, because of persisting glycosuria in the absence of hyperglycemia. It is believed that 7 of these persons may become diabetic because of widely fluctuating blood sugar levels. In view of Dewees and Langer's[27] observations that in a large number of persons with apparent nondiabetic glycosuria there later developed diabetes, this total group would be a worth while source of future study.

Of the 43 subjects retested because of hyperglycemia alone on the first test, 8 were later classified as probably having diabetes. The average venous reading on the first test was 189 mg. per hundred cubic centimeters. In 8 of these 43 persons retested we did not consider a diagnosis of diabetes justified, and they were classified hyperglycemia without glycosuria. The remaining 27 persons had normal blood sugar levels on all subsequent tests.

A worrisome phenomenon was the fact that some of these persons exhibited an abnormal postprandial blood sugar level without manifesting glycosuria, even on subsequent dextrose tolerance tests. Is this a prediabetic state or a functionally slow utilization of carbohydrate? Mirsky[28] does not believe that the diagnosis of diabetes is dependent on the presence of sugar in the urine but believes that many such cases are metabolically diabetes mellitus.

Blood Sugar Level of Nondiabetic Persons Tested.—An interesting supplement to the diabetes case-finding program was the determination of the blood sugar level for a large series of persons with nondiabetic laboratory results. For 1,353 persons the venous blood sugar level was determined from a specimen taken sixty to ninety minutes after a meal. There were also available for study 1,026 capillary blood specimens fulfilling this time requirement for purposes of comparison.

In general there appears to be little difference between the blood sugar levels for males and females at any given age, however, there does tend to be a rise in the blood sugar level with advances in age.

The average blood sugar level increases with age, as does the proportion of persons with values above the average level. At age 15 to 24, the only group with a large enough number of both venous and capillary specimens to permit direct comparison, there is a difference of 20 mg. per hundred cubic centimeters between the average venous and capillary blood sugar level.

Ratio of Diabetes Cases to Portion of Population Studied.—The prevalence of diabetes by age and sex among the 4,983 persons in Oxford is detailed in table 4. The testing and survey program revealed that there were 40 diabetic persons in Oxford under treatment, and 30 more cases of the disease were discovered. If the total Oxford population is used as a denominator, conservative figures would show an incidence of 0.8 per cent known cases of diabetes and 0.6 per cent newly discovered, or a total incidence of 1.4 per cent.

However, since 29.4 per cent of the townspeople were not reached by the testing program, it is estimated that the number of previously undiscovered cases of diabetes which might have been found had all the townspeople been tested would perhaps be as large as 47. The 40 known cases plus 47 estimated cases are equivalent to 87 cases among 4,983 persons, or 1.7 per cent of the population in Oxford.

Illustrative Case Histories.—Although all authorities in the field of diabetes mellitus do not agree on the precise blood sugar level for the diagnosis of the disease, most will recognize that the 30 cases diagnosed as diabetes in the study are abnormal and conform closely to the laboratory and clinical picture of the disease. (See table 5 for pertinent data and laboratory observations for these cases.) It is our belief that 25 of the cases would be considered diabetes by most clinicians.

% in group tested ‡......	100.0			97.3			2.0			1.1			0.9											

* The negative group includes all those persons rechecked but found to have neither diabetes nor persistent glycosuria or hyperglycemia.

† This estimate is based on the assumption that the percentage of persons in each age group discovered to have diabetes during the survey would prevail had all persons been reached by the testing program. For example, we found 4 new cases in the age group from 35 to 44. Since we tested 71.5 per cent of that group, we might assume that the number of new cases in this age group should be expanded to a total of 100/71.5 times that number, or 5.6 cases. It is believed that the number of "known" cases should not be expanded, since an intensive effort was made to locate all known cases of diabetes. This factor naturally makes the percentage of diabetic persons in the population smaller than that per cent in the sample—1.7 as compared with 2.0 per cent.

‡ The rest of the group tested includes 8 persons with proved hyperglycemia and 17 with persistent glycosuria, who composed 0.7 per cent of the whole.

28. Mirsky, I. A.: Personal communication to the author.

Since a basic purpose of the demonstration is to show the value of early diagnosis, an illustrative case is reported:

Case 93.—A boy aged 16, a student, had no previous complaints. His grandmother died with diabetes mellitus. On his initial test he was found to have glycosuria of 0.4 per cent and a capillary micro blood sugar of 175 mg. per hundred cubic centimeters an hour after a full meal. The second test revealed glycosuria of 0.5 per cent and a capillary blood sugar level of 190 mg. an hour after eating. Two dextrose tolerance tests were done several weeks apart, with the following results: The fasting, one hour, two hour and three hour values for urine sugar were 0.4, 0.7 and 0.3 per cent, and a trace; values for venous blood sugar after the same intervals were 96, 185, 128 and 90 mg. per hundred cubic centimeters.

Admittedly this person's blood sugar level barely reaches the minimal diabetic standards. It is possible that his blood sugar curve may be the "alimentary" type described by Wilder.[29] However because of both the history of diabetes in the family and our laboratory observations we have considered him a potential diabetic, and he is at present under observation and dietary treatment by his family physician. The educational committee of the American Diabetes Association is particularly interested in following this patient, because this may be the type of case in which early discovery plus prompt treatment may prevent frank diabetes.

The following case illustrates the value of a complete urinalysis as an essential part of a physical examination.

Case 3297.—A man aged 55, a mill worker, complained of malaise, weakness and occasional transitory numbness and neuritic pains in the extremities at night. His efficiency at work was impaired. After a fainting spell at work, he was given a physical examination, but no test was made for sugar in the blood or urine. Later a diabetes test by one of the survey teams showed a urine sugar of 2 per cent and a capillary blood reading of 180 mg. per hundred cubic centimeters. A second test showed 2.4 per cent urine sugar and a venous blood sugar of 290 mg. The diagnosis of diabetes was confirmed by his family physician, and he is now under treatment.

Analysis of Data on Diabetic Persons.—From information provided on the history form, we have analyzed certain data about the 40 previously known and the 30 newly discovered diabetic persons, a summary of which follows:

Age: The ages of the newly discovered diabetic persons varied from 16 to 93, while the median age was 55 years. Those from 45 to 64 years of age constituted over half of the new cases.

Table 6.—*Per Cent Overweight or Underweight for Seventy Diabetic Persons in Oxford, Mass., at Time of Maximum Weight*

% Overweight or Underweight	Number of Persons: Newly Discovered M.	Newly Discovered F.	Known M.	Known F.
Overweight				
40 to 45.9	..	..	..	3
30 to 39.9	..	..	..	5
20 to 29.9	3	4	5	2
10 to 19.9	3	5	3	8

Less than 5% above or below average	3	1	2	1
5% or more underweight	2	1	1	1
Not stated	2	1	1	4
Total	16	14	15	25

Among the 40 known diabetic persons, the youngest was aged 19 and the oldest 78. The median age of the group is 59.5 years.

The duration of diabetes in the known cases ranged from a few months to thirty years. Five of the patients had diabetes of twenty or more years' duration. For the whole group the average duration was approximately 8.6 years.

Table 7.—*Comparison of Diabetic and Nondiabetic Population of Oxford, Mass., with Relation to Family History of Diabetes for Ages 15 and Over**

Unknown	1	1.4	..	1	89	3.6	45	44

* Excludes 25 persons with either hyperglycemia or glycosuria not diagnosed as diabetes.

Sex: There were 31 men and 39 women in the series of cases. The small difference in prevalence between the two sexes is shown by the fact that 1.7 per cent of the men in Oxford were diabetic as compared with 1.8 per cent of the women (table 6). This ratio is different from what might be expected on the basis of general mortality data showing higher diabetes death rates for women than for men.

National Origin or Descent: It has already been mentioned that the predominant racial groups in Oxford are those of French or French-Canadian descent. Among the diabetic persons there, 29 were of French descent, 15 were of English or Scotch descent and 26 represented all other groups.

Although the incidence of diabetes among the French group was much higher than for any other nationality, it is impossible to draw definite conclusions from this fact because of intermarriage of racial groups and the small numbers involved. These observations are of interest, however, in view of Blotner's [7a] report of a relatively high prevalence of the disease among the French. We believe that testing any discrete group for diabetes would augment the evidence for the universality of the disease.

Family History of Diabetes: The results of this study bear out the previous belief that a family history of diabetes is reported more frequently by diabetic than nondiabetic persons (table 7). For those over 15 years of age, a family history of diabetes was reported by 38.6 per cent of the diabetic persons and 18.2 per cent of the nondiabetic. Among the younger adult diabetics, from 15 to 44 years, a family history of the disease was extremely prevalent, since 8 of the 13 patients reported it. Among the younger adults who were not diabetic, this family history was reported by 20.2 per cent. Not only is a family history of diabetes more pronounced among diabetic than among nondiabetic subjects but it is of interest to observe that this family history was frequently reported by nondiabetic persons —in 18.2 per cent of 2,490 adults.

An illustration of this pronounced familial tendency in diabetes is shown by cases 1585, 1601 and 1803, in which the disease was found in a father aged 84, in his daughter aged 55 and in his son aged 53. On first interview all 3 denied a known history of diabetes in the family. The son had been about 15 per cent overweight at the time of his maximum weight and the daughter, about 10 per cent overweight. The father was underweight at the time of the survey, but his past weight history is uncertain because of his advanced age.

---

[29] Wilder, R. M.: Clinical Diabetes Mellitus and Hyperinsulinism, Philadelphia. W. B. Saunders Company, 1940, p. 31.

Overweight: The occurrence of overweight at some period of their lives was reported by most of the diabetic persons in this series; at the time of their maximum weight 20 of the 31 men and 30 of the 39 women had been overweight. (In this study overweight was considered as 5 per cent above average for weight and height according to the standard Metropolitan Life Insurance Tables.) Table 6 illustrates the degree of overweight observed in these cases.

Symptoms: This study shows that many of the symptoms and observations commonly associated with diabetes are not recognized by the patient. Among the newly discovered cases such a classic symptom as polydipsia occurred in 10 patients, while 8 reported polyuria. The public needs better acquaintance with the symptoms of diabetes, which generally are considered to be well known. Only 5 of the new patients on careful questioning reported no symptoms at all, although in a few the symptoms manifested were vague nes, such as malaise or a feeling of tiredness.

Some significant symptoms reported by the 30 newly discovered diabetic persons follow, in the order of their requency: cramps or pains in extremities, reported 10 times; polydipsia, 10; weight loss (5 per cent or more), 10; polyuria, 7; pruritus, 7, and polyphagia, 2.

Severity of New Cases: On an empiric basis of glycosuria, degree of hyperglycemia and number and severity of symptoms, the 30 new cases of diabetes could be classified as follows: severe 9; moderate 7; mild 9, and early or "probable" 5.

Method and Degree of Control in Known Diabetic Persons: Generally the known diabetic patients in Oxford appeared glad of the opportunity to have a blood test and urinalysis. Another 18 diabetic persons from nearby areas requested the tests, but their results are not reported with this data.

An attempt was made to evaluate the condition and degree of control of the diabetic patients in Oxford. For purposes of comparison, we have designated good control as glycosuria under 1 per cent and a blood sugar level under 200 mg. per hundred cubic centimeters (venous) an hour after a full meal. By these standards 17 of the 40 patients were satisfactorily controlled, while the others had excess glycosuria or hyperglycemia and, in many instances, active symptoms. Two diabetic patients in Oxford were not tested during the study but were reported by their physicians.

At the time of the survey 24 of the diabetic persons were taking insulin, with daily dosages ranging from 4 to 82 units. The average daily dosage was 21 units. Six other patients had taken insulin previously but later omitted its use.

The diet of the patients tested was not determined in great detail. Seven apparently followed a rigid diet. The most commonly reported description of diet was "restricted." Nine reported either no dietary restrictions or negligible ones, such as "no sweets."

COMMENT

1. The results of this study indicate the unreliability of the fasting blood sugar level as a means of diagnosing early diabetes. Only 3 of the 14 dextrose tolerance tests completed in the diagnosis of the new cases had a fasting blood sugar value of 130 mg. per hundred cubic centimeters (venous) or higher; in these cases the readings were 280, 178 and 132 mg. All the others had fasting blood sugar levels below 130 mg., even though the subsequent blood sugar levels were as high as 280 mg. one or two hours after the ingestion of dextrose. (See table 5 for a summary of the symptoms and laboratory data on the 30 new cases of diabetes.) As a single diagnostic procedure tests of blood and urine taken an hour after a full meal constituted a more useful index than fasting blood and urine tests.

2. The results of the tests show the necessity of using both blood and urine tests as a screening device to diagnose diabetes. If urinalysis alone had been employed in this study 8 cases of diabetes would have escaped diagnosis. Moreover, if only blood specimens had been taken 6 cases would have escaped detection. In addition, it is highly undesirable to tell a person that he has no diabetes on the basis of just one of these tests and to have symptoms of the disease develop later.

3. One of the problems experienced was the necessity of retesting 123 subjects with only glycosuria on the first test in order to locate 6 cases of diabetes. In the future this difficulty may be avoided by making chemical tests which would eliminate reducing substances other than dextrose.

4. Benedict's qualitative test for urine sugar is considered to be practical and accurate for use in a large scale testing program.

5. For large scale screening purposes simpler methods of accurate, rapid blood sugar testing are needed. Intensive efforts are being made in this direction.

6. It is conceded that a definite diagnosis of diabetes, particularly in the milder cases, often cannot be made except on the basis of repeated tests of urine and blood over a period of several months. The new cases in this series will be observed further in an effort to exclude the possibility of transient hyperglycemias or glycosurias.

SUMMARY

1. Recent estimates have indicated a widespread prevalence of diabetes.

2. Clinical and experimental studies by others indicate the value of early diagnosis of diabetes.

3. A diabetes mellitus study based on history, urine and blood sugar tests and dextrose tolerance tests was made by the United States Public Health Service on 3,516 persons in Oxford, Mass., a typical American town. This number represents 70.6 per cent of the entire population of 4,983.

4. A total of 70 cases of diabetes were found. This included 40 cases previously known and 30 discovered during the study. This was a prevalence of 2.0 per cent of those tested.

5. Probably every known diabetic person was listed, but there were believed to be additional undiscovered cases among the remaining untested portion of the population. For the entire population of 4,983, the prevalence of diabetes in Oxford is 1.4 per cent (0.8 per cent old and 0.6 per cent new cases). Projecting the figure of the 1,400 untested cases on the basis of the observations in the tested cases, the prevalence of diabetes in Oxford would be 1.7 per cent.

6. For every 4 previously known cases there were 3 more hitherto undiscovered and unsuspected cases.

7. The large ratio of new to known cases which was observed in this study indicates a probable prevalence

of diabetes in the United States higher than that hitherto reported.

8. Among the 70 cases of diabetes observed there were 31 men and 39 women. The median age of the known diabetic persons was 59.5 years and that of the new patients was 55 years.

9. The prevalence of the disease among French Canadians was high, but this group is predominant in the tested area.

10. A family history of diabetes was found in 38.6 per cent of the cases of diabetes and in only 18.2 per cent of the nondiabetic cases.

11. Many of the patients with newly discovered cases reported symptoms commonly associated with diabetes but yet were not aware of the significance of those symptoms.

12. An evaluation of the condition of the persons known to have diabetes indicates a need for improvement in the control of the disease by the patient.

13. Diabetes is much more prevalent than is commonly supposed, with large numbers of unrecognized cases of the disease in each community. Application of ways and means of discovering diabetes early by means of simple, effective tests is necessary in order that prevention may be obtained in early potential cases and that those with easily recognizable diabetes may receive adequate care early, and thus escape many of the complications of this disease.

JUNCTION NEVUS—NEVOCARCINOMA

(The So-Called Melanoma Group)

WILBERT SACHS, M.D.
GEORGE MILLER MacKEE, M.D.
OSCAR D. SCHWARTZ, M.D.
and
HERBERT S. PIERSON, M.D.
New York

Of the numerous problems associated with the pigmented nevi, those concerned with the diagnosis and treatment of the junction nevus and nevocarcinoma (melanoma) are the most important. By the presentation of an orderly concept of junction nevus and nevocarcinoma, it is the purpose of this discussion to provide a working basis for their management.

Terminology.—We do not favor the term melanoma, as it is used loosely at times to denote any type of pigmented nevus; and it is ambiguous, as it refers both to a certain type of nevus and to the malignant growth which develops from it. We prefer the terms junction nevus and nevocarcinoma since they are more specific and more descriptive and eliminate the previous objections.

Junction nevus is a cellular nevus in which nests of nevus cells can be seen with ease in the basal cell zone. It is called junction because it arises at the junction of the epidermis and cutis. The reason for the name nevocarcinoma is self-explanatory. These terms have not originated with us and have been used in the past. Junction nevus is synonymous with melanoma, benign melanoma, epidermic-dermic nevus and schwannoma. Nevocarcinoma is the same as melanoma, malignant melanoma, melanocarcinoma, melanoblastoma and melanosarcoma; nevocarcinoma without pigment is identical with amelanotic melanoma.

JUNCTION NEVUS

Clinical Description.—Junction nevus usually is described as a pea-sized, flat or slightly raised, smooth, nonhairy lesion of a deep brown to black color. However, the lesion may vary in size from 1 mm. to several centimeters, extend considerably above the surface, be verrucous, have hair and be nonpigmented. Further, the criteria enumerated in the clinical description are observed, at times, in other dermatoses.

The following diseases should be considered in the clinical differential diagnosis: other pigmented nevi, such as intraepidermic epithelial, intradermic epithelial and blue nevi; basal cell epithelioma with pigment, hematoma, granuloma pyogenicum, angioma, thrombotic angioma, glomus tumor, seborrheic verruca, spiradenoma and single lesions of Kaposi's sarcoma and leukemia. Aside from the clinical features, the age of the patient, the history and location of the lesion, subjective symptoms and examination of the blood are helpful, but a biopsy is of prime importance in making a conclusive diagnosis.

Biopsy.—The microscopic picture of junction nevus is definite, and the diagnosis can be made easily. However, differences of opinion exist as to the advisability of removing such tissue. Some believe that this may initiate activity in the lesion, while others consider that biopsy is necessary and not contraindicated. We agree with the latter group for the following reasons:

First, we have studied tissue on which numerous clinical diagnoses other than junction nevus have been made. Even though the microscopic diagnosis proved to be junction nevus, we have never known cancer to develop as a result of this practice, nor has biopsy increased the degree of malignancy in existing nevocarcinoma.

Second, there is often no alternative to biopsy, for on such sites as the nail bed, fingers, toes, penis, vulva, nose, eyelids, lips and in the mouth suspected lesions cannot be removed by wide excision without causing serious disfigurement and damage. Since there are many relatively benign lesions which may simulate junction nevus and nevocarcinoma we consider that this type of operative procedure is not justified without a definite microscopic diagnosis.

Third, many authorities have stated their belief that there is practically no possibility of disseminating tumor emboli to distant parts by the careful removal of material for biopsy. Among these are Wood,[1] Ewing,[2] Hellwig,[3] Boyd,[4] Donnelly[5] and Satenstein.[6] MacKee and Cipollaro[7] have stated that "The advantage of and the necessity for a careful microscopic examination are now fairly well understood by the medical profession. Formerly, it was considered dangerous to perform a biopsy in the presence of a malignant neoplasm. It is now the consensus of opinion among students of cancer that a properly conducted biopsy is without danger."

Microscopic examination should be made in all cases of suspected junction nevus and nevocarcinoma, either to establish or corroborate the diagnosis. Small lesions should be removed entirely and then examined; from

larger lesions a small piece about 0.5 cm. in diameter is sufficient for examination. Reports on such biopsies should be made within a few days, and the necessary treatment should be instituted promptly.

Microscopic Features.—While the clinical diagnosis of junction nevus offers some difficulty, the histologic picture is distinct, and only some of the other pigmented nevi and the transitional stage between the nevus and the cancer need be differentiated. The remaining dermatoses, although clinically suggestive of junction nevus, exhibit entirely different microscopic features.

Junction nevus is composed entirely of nevus cells. In the cutis these cells may be few or abundant, diffuse or compact, and may be arranged in small groups simulating glandular tissue. In the lower part of the epidermis are spaces containing several nevus cells, called cell nests, and about them the basal cell margin is missing. Hair follicles usually are not present but in some instances are seen; at times pigment may be absent. The clear cells (cellules claires) supposedly characteristic of this nevus, although sometimes helpful, are by no means pathognomonic, as they may be demonstrated in other diseases. There is no inflammatory reaction.

Nevus cells are about the same size as, and appear not unlike, individual prickle cells. The shape is influenced by the degree of crowding, but they are seldom round. There is no connection between one cell and the other, and the cellular outlines are clear. The cytoplasm is distinct, well stained and somewhat homogeneous. The nuclei are round or oval, vesicular and not deeply stained; frequently the cells are multinucleated. Varying amounts of both extracellular and intracellular pigment are seen.

The intraepidermic type of epithelial nevus shows no similarity, microscopically, to the junction nevus. The process is entirely epidermic, and no nevus cells or cell nests are present. The intradermic nevus, however, resembles the junction nevus, but the nevus cells are not connected with the epidermis and there are no cell nests.

Any combination of these nevi may be noted in the same lesion. In such a case the clinical features of the junction nevus are entirely masked and can only be determined microscopically.

The blue nevus (Jadassohn-Tieche) is also composed of nevus cells, but these are of connective tissue, not of epithelial origin. The cells are elongated, spindle-shaped and produce melanin. They may be located anywhere in the cutis but often are about the adnexa. The cells may be few or many, localized in one portion or diffused throughout the cutis; cell nests are never found.

NEVOCARCINOMA

Malignant change in a junction nevus results in a nevocarcinoma. This alteration may be insidious or rapid. Although signs of this change may be detected clinically, alteration in the character of the cells or the extension of the process may be so gradual as to give no visible evidence of its occurrence. Thus the transformation would be revealed only by the microscopic observations. MacKee and Cipollaro[7] have stated that: "A carefully performed biopsy and painstaking microscopic study are often necessary for an unequivocal diagnosis. In the case of malignant neoplasm such study furnishes valuable information relative to type and grade of malignancy, stage of evolution, invasiveness, metastasis, prognosis, . . . and serves as a guide in the selection of the best therapeutic method or methods."

We subdivide nevocarcinoma into early or late stages based on the degree of malignancy found, rather than on a time factor. Early nevocarcinoma may be present, even though the lesion has existed for considerable time, and late nevocarcinoma may be of short duration.

Alteration in size, color, surface, ulceration, inflammation, scaling, bleeding, crusting or tenderness may be observed in those lesions which show clinical variation from the original nevus. In late nevocarcinoma the lesion has many of the changes mentioned, and these are accentuated. There may also be lymph node involvement and metastasis. Even without evident metastasis or enlarged lymph nodes, the pathologic observations may be sufficient to prognosticate such occurrence.

The differential microscopic features of junction nevus and early nevocarcinoma are few. The differential diagnosis, although in some cases difficult, usually can be established. In early nevocarcinoma some embryonic or anaplastic cells are present. Frequently these cells may be demonstrated either coming off the epidermis in areas of the cell nests or in the subepidermic zones. Mitotic figures are usually but not always visible. There may be a mild inflammatory reaction in this stage, and changes in the amount of pigment are not significant.

In late nevocarcinoma practically all the cells are anaplastic; they are large and have a tendency to become round, and they vary in size and somewhat in shape. The cytoplasm is granular, not homogeneous; the cell walls are distinct, and the nuclei are increased in size.

In any consideration of nevocarcinoma the subject of trauma is emphasized. It is our opinion that the clinical changes previously mentioned may occur with or without trauma. Injury may be slow and gradual, as in shaving, combing, irritation from articles of clothing or exposure to pressure. On the other hand the trauma may be specific and rapid, as by a blow or bruise. It is impossible to foretell from the type of trauma the likelihood of subsequent malignant change; nor is it possible to correlate the type and degree of trauma with the type and degree of ensuing malignancy. Improper treatment of the junction nevus is a form of trauma and may be followed by early or late nevocarcinoma.

COMMENT

In the management of pigmented nevi it is of prime importance to establish an exact diagnosis. The clinical features of junction nevi and even of nevocarcinoma are not always diagnostic, and other dermatoses must often be considered. The other pigmented nevi probably offer the greatest difficulty in the clinical differential diagnosis.

Nevus pigmentosus, nevus pigmentosus et pilosus, nevus pigmentosus et verrucosus and the like are inadequate diagnoses. They give little information as to the true nature of the lesion, and several types of nevi can fit the same diagnosis. The common pigmented nevi are classified by Satenstein[6] as epithelial; those of epithelial origin, which includes the epidermic; the dermic and epidermic-dermic, or junction nevus, and mesenchymal, those of mesodermal origin represented by the blue nevus.

The epidermic pigmented nevus is superficial, raised, verrucous, light to deep brown color, from one to several centimeters in size, and usually has some long thick black hairs. The differentiation of this lesion from junction nevus offers little trouble.

The so-called common mole is usually an intradermic nevus classified clinically as nevus pigmentosus or, if it contains hair, nevus pigmentosus et pilosus. The common mole may occur on any part of the cutaneous surface with predilection for the face. There may be a single lesion; often they are multiple. The lesions may be flat, but usually they are elevated. In size they range from a few millimeters to one or more centimeters. The color may be that of normal skin or any shade of brown; hairs may or may not be present, and the surface is usually smooth. They usually develop early in life and remain stationary. When one is certain of the diagnosis of intradermic nevus, the consensus is that the mole can be let alone or treated in any conventional manner—by electrolysis, for instance.

Clinically the blue nevus is almost identical with the junction nevus, and a microscopic diagnosis is necessary to distinguish between them. We have not seen malignant change in a blue nevus.

Patients usually are advised to have the junction nevus removed by wide excision or to leave it untreated. The first results in unnecessary scarring and disfigurement, and the second is dangerous. As the junction nevus is the precursor of nevocarcinoma (a precancerosis) it should be removed, but the nevus is all that need be excised.

When malignant change develops there are different gradations, and the therapy and prognosis vary accordingly. It has been customary to regard the diagnosis of nevocarcinoma with despair. As previously mentioned, we divide the disease into early and late stages and believe that many cases of the early malignant stage can be cured and that the prognosis, while serious, is more hopeful. Here, the lesion should be removed by wide excision and followed at times by radiation therapy. In late nevocarcinoma the prognosis is grave, but radiation therapy and surgical measures should be tried, as this combination is successful at times.

From the foregoing histologic and brief clinical descriptions, it is evident that caution is necessary in the management of any lesion with features suggestive of a junction nevus. As previously indicated, there are many nevi, both cellular and noncellular, that are harmless; therefore a correct diagnosis is important. There are a number of features that clinicians have thought to be indicative of danger or safety. These consist of color, presence or absence of hair, flatness or elevation, character of the surface, the number of lesions, size, development in early life and subsequent quiescence. Unfortunately, none of these features is a safe guide, although each is of some help. As a rule there is no hair in a junction nevus. The color is more likely to be blue-black, black or slate gray than some shade of brown or normal skin color. The junction nevus may be flat, but more often it is elevated, single and small. The surface may be smooth, but it is more likely to be uneven. A change in size or in the surface is a danger sign.

When there is any doubt about the histologic type, we repeat that it is our opinion that the lesion should be excised or a biopsy performed.

SUMMARY

1. The junction nevus (melanoma, benign melanoma and so forth) is the only forerunner of the nevocarcinoma (melanoma, malignant melanoma and the like).

2. The nevus cannot always be diagnosed clinically, for many dermatoses may present similar features.

3. Biopsy is essential for a positive diagnosis and is attended by no danger if properly performed.

4. Junction nevus should be considered as a precancerosis and as such should not be left untreated. It should be removed to preclude completely the possibility of nevocarcinoma.

5. Nevocarcinoma is too inclusive and should be divided into early and late stages. Many cases of the early stage can be cured by wide excision and radiation therapy. In the late stage the prognosis is grave.

INTRATHORACIC GASTRIC CYSTS

EDGAR W. DAVIS, M.D.
Washington, D. C.
and
DAVID SALKIN, M.D.
Hopemont, W. Va.

Congenital intrathoracic mediastinal cysts may be classified as dermoid, teratomatous, pericardial, simple, lymphangiomatous, bronchial and alimentary. The alimentary group includes cysts which have esophageal, gastric or intestinal characteristics. To July 1946 the literature contained only 25 reports of cysts having gastric features. Eighteen of these showed only gastric mucosa and 7 cysts showed in addition esophageal, intestinal or even bronchial mucosa.

The first gastric cyst was reported by Staehelin-Burckhardt in 1909.[1] Prior to 1940, 11 such cysts were described.[2] Since then 14 more cases were added, and 12 of these occurred in the United States.[3] This greater frequency in the past seven years is due to the increasing use of the roentgen ray and to exploratory thoracotomy. The lag of case finding in other countries is probably due to the disruptions caused by the war, and more reports may be expected in the near future. Despite its rarity, the disease merits attention because it is amenable to surgical treatment.

REPORT OF CASE

History.—B. J. F., a white girl aged 14, was admitted to Hopemont Sanitarium with a chief complaint of pain in the right side of the chest. She had felt well up to the age of 7 years but then noted an insidious onset of a dull, aching pain in the right upper posterior portion of the chest. This pain recurred every four or five months and lasted two or three weeks. There was no radiation. She felt as though she lay on a mass the size of her hand. The last attack occurred one month prior to admission, at which time a roentgenogram was made which was suggestive of a tumor. She had no cough, expectoration, hemoptysis or dysphagia but was moderately dyspneic on mild exertion. The past history was noncontributory.

Examination.—The patient was a slender girl 62 inches (157 cm.) tall and weighed 91 pounds (41 Kg.). General physical examination of the head, neck, abdomen and nervous system revealed essentially normal conditions. The pulse rate was 90, the blood pressure was 110 systolic and 68 diastolic in each arm, and the heart showed no abnormalities. The respiratory rate was 22, and the patient manifested moderate dyspnea on slight exertion. The cutaneous veins of the thorax were prominent, and there was a mild scoliosis to the left side. The left hemithorax was normal. The right side showed dulness and absence of breath sounds over the upper two thirds of the chest posteriorly; the anterior surface showed impaired resonance and faint breath sounds over the upper portion; the lower third of the chest was normal.

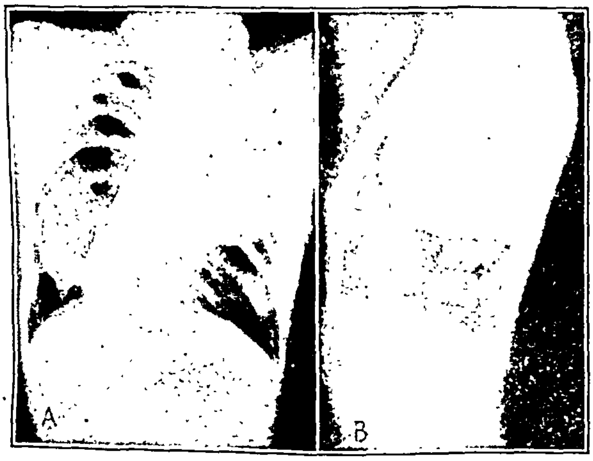

Fig. 1 (*A* and *B*).—Posteroanterior and lateral roentgenograms showing the tumor.

Urinalyses and blood studies were within normal limits. The sputum was negative for Mycobacterium tuberculosis, and serologic tests of the blood were negative for syphilis.

Roentgenologic studies included fluoroscopic examinations and films of the chest and spine, bronchograms and esophagrams (fig. 1). In the right side of the chest there was a 15 cm. oval, homogeneous, sharply defined mass occupying the upper two thirds of the chest and situated posteriorly. The heart was in normal position, but the trachea was displaced to the left side. Other roentgen observations included a thickened fissure between the upper and middle lobes of the right lung; calcification in the right tracheobronchial lymph nodes; a mild scoliosis of the dorsal spine with convexity to the left and centered at the sixth and seventh vertebrae; incomplete fusion of the arches and spinous processes of the seventh cervical and first dorsal vertebrae, and a mild erosion of the posteromesial segments of ribs three to six inclusive on the right side. Bronchograms revealed a pronounced compression of the lower trachea and the right stem bronchus, and the bronchus of the upper lobe of the right lung was completely occluded; the bronchi of the middle and lower lobes were normal. The esophagrams showed some displacement of the esophagus to the left but revealed no other abnormalities.

The clinical diagnosis was that of a tumor mass. It occupied the right hemithorax, originating in the posterior mediastinum, and probably was a neurofibroma.

Operation.—The tumor mass was removed Aug. 24, 1944 with the patient under endotracheal cyclopropane anesthesia. With the patient on the left side, a posterolateral incision was made, the seventh rib was removed and the pleural cavity was entered through the periosteal bed. The upper two thirds of the chest was so filled by a large, firm, brownish black mass that the sixth, fifth and fourth ribs had to be transected posteriorly to permit an adequate exposure. The mass was oval and corresponded to the roentgen measurements of 15 by 14 by 10 cm. Its anterior surface was densely adherent to the lung and, on freeing it, several dense black areas measuring 5 mm. were uncovered. One of these began to show an oozing of greenish black fluid, and then the fluid shot out with such force that it formed a stream of about 15 cm. in height. The mass was so hard that, until then, it was thought to be solid. The rest of the fluid was aspirated, and in all 1,000 cc. of it was collected. The first portion of the fluid was thin, but the last portion was thick and gritty. The wall of the cyst then contracted considerably the freed from the surrounding structures and rem p The pedicle was wide and was adherent to o

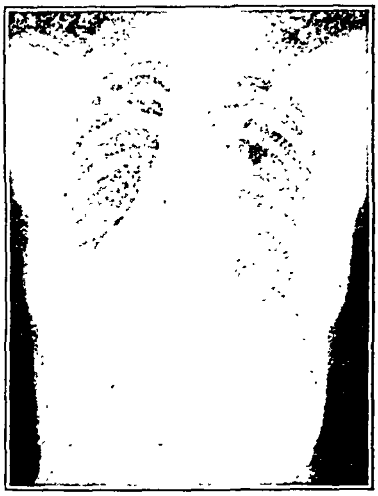

Fig. 2.—Roentgenograms of chest made May 14, 1946, or about twenty months postoperatively.

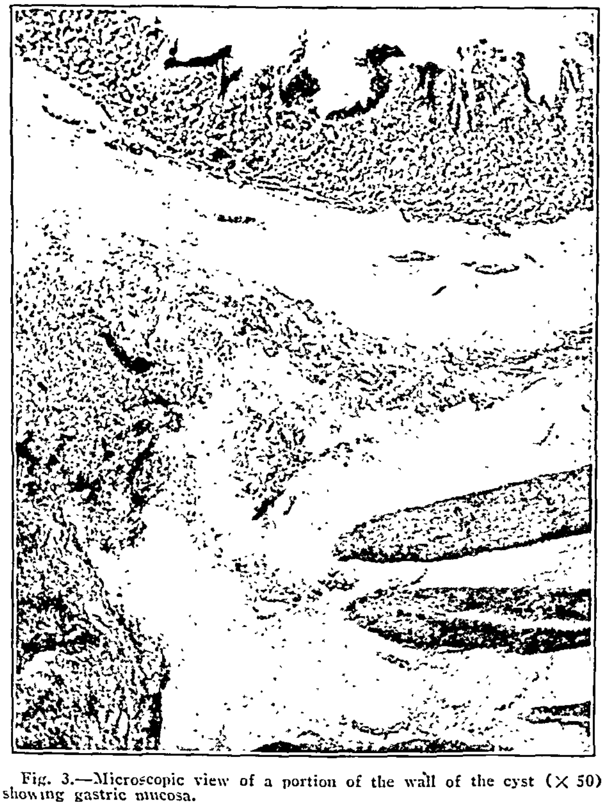

Fig. 3.—Microscopic view of a portion of the wall of the cyst (× 50) showing gastric mucosa.

fourth to the seventh inclusive, and from the vertebral bodies to the angles of the ribs. The lung was then inflated and the chest cage closed without drainage.

The postoperative course was uneventful. The cutaneous thoracic veins became less prominent, there was no dyspnea even on considerable exertion and the pain disappeared. Now, almost three years later, the girl is 65 inches (165 cm.) tall, weighs 135 pounds (61 Kg.), is very active and has no symptoms (fig. 2).

Pathologic Examination.—The specimen, preserved in solution of formaldehyde, was examined by the Army Institute of Pathology. The flattened cyst measured 10 cm. in diameter, and the wall varied from 2 to 5 mm. in thickness. The inner surface was mottled reddish black and white; the dark areas were composed of blood covering irregular shallow ulcers, and the light areas were smooth and resembled mucosa. One area near the pedicle measured 2 cm. and showed typical gastric folds.

Microscopic examination (fig. 3) revealed the white areas to consist of gastric mucosa mainly of the pyloric type. There was a distinct muscularis mucosa and submucosa. The muscularis was composed of two layers of smooth muscle; the outer layer was narrow and homogeneous and the inner layer was composed of numerous muscle bundles. In many areas the mucosa showed erosion and destruction. Hemorrhage was present in the submucosa and muscularis, and some of the old hemorrhagic areas showed occasional acicular cholesterin clefts and macrophages filled with pigment. Deposits of calcium were present in some sections. Numerous foci of lymphocytes and plasma cells occurred. One small intramural lymph node was also present. The vessels exhibited decided thickening of their walls and narrowing of the lumens. Rudimentary Meissner's and Auerbach's plexuses were present. In the periphery numerous bundles of nerves were seen. There was a layer of serosal cells covering part of the outer shaggy fibrous layer.

The pathologic diagnosis was gastric cyst with ulceration. Unfortunately, the fluid was contaminated with blood and was not saved for chemical examination.

REVIEW OF LITERATURE

Pathologic Data.—The cysts are located paravertebrally in the posterior mediastinum and expand retropleurally into either hemithorax; 18 cases occurred in the right side and 5 in the left; 3 were placed centrally. The cysts are spheric, oval or pyriform and are situated anywhere along the entire length of the mediastinum; they may occupy a small or large part of the thorax, depending on the size of the cyst and the age of the patient. The cysts described vary from 3 to 15 cm. in diameter. The cyst wall measures from 1 to 5 mm. in thickness and shows the regular alimentary layers. There is no serosa, but the reflected pleura resembles it. The muscularis shows two (and occasionally three) layers and may present ganglion cells, nerve trunks and sometimes calcification. The submucosa may show hemorrhage and an inflammatory exudate. The muscularis mucosa is well defined. The mucosa may be thrown into gastric folds and present deep branching glands, chief and parietal cells. Peptic ulcers occurred in 7 cases.

The cysts may be densely adherent to the adjacent structures and may show pressure effects on the mediastinal vessels, nerves, ribs and vertebrae. The esophagus may show pressure necrosis, and the lungs may present atelectasis, chronic pneumonitis and bronchiectasis. In 4 cases a peptic ulcer perforated through the cyst wall into a bronchus. The cyst fluid may assume any color and has been described as amber, greenish, yellowish, milky and brownish. It may be thin or gritty. It is usually acid but may be neutral and may contain hydrochloric acid and pepsin. The proportion of other anomalies in these cases is high and includes scoliosis, hemivertebrae, spina bifida and abdominal enteric cysts and diverticula.

There are three theories advanced to explain the origin of the cysts. Lewis and Thyng [4] have considered that the cysts are caused by an embryonic diverticulum or an outpocketing of epithelial nodules capable of producing gastric mucosa. Keith [5] has stated the opinion that they are caused by a failure of coalescence of the vacuoles in a transverse manner when the alimentary tube is in a solid state, resulting in a cyst which may or may not be closely attached to it. Black and Benjamin [2b] have expressed their belief that the cysts are intrathoracic vestiges of the vitelline duct.

Clinical Aspects.—The patients ranged from premature stillborn infants to adults 23 years of age, but 22 of the 26 patients were under 4 years of age. Five were stillborn or died shortly after birth, 9 were under 1 year of age and 8 more were under 4 years of age. The others were aged 10, 14, 15 and 23 years. The males showed a predominance, with 15 cases occurring in boys, 10 in girls, and the sex not stated in 1 case; however, this may not be the actual state of affairs, for there were 7 females in the 15 cases reported since 1940.

The common symptoms are dyspnea, cyanosis, cough and hemoptysis; the others include pleurisy, attacks of pneumonia, pain, regurgitation of food, hematemesis, dysphagia, fever and malaise. The symptoms are produced by the pressure of the cyst on the mediastinal vessels, and its effect on the lung and esophagus are as described. There are no specific signs, and in fact no signs may be present. The cyst itself results in dulness and absent breath sounds, and the presence of inflammation in the lung may result in altered breath sounds, dulness and rales. The heart is usually displaced to the opposite side.

The roentgen examination reveals a well defined, rounded, homogeneous shadow placed posteriorly. However, details may be obscured by pulmonary changes or by a pleural effusion. The lung may show compression, atelectasis or infiltrations. The heart and trachea may show displacement. Bronchograms may show evidence of bronchial displacement, obstruction and bronchiectasis; in 1 instance it showed a bronchocystic fistula. Esophagrams reveal only secondary changes such as displacement, but no case described manifested an intraluminal connection with the cyst. The bony thorax may show the anomalies and pressure effects described.

Bronchoscopic study may disclose narrowing of the trachea and bronchi due to extrinsic pressure and an inflamed mucosa and secretions resulting from pulmonary changes.

There is no specific means of diagnosing a gastric cyst except when it is aspirated erroneously and the fluid is found to resemble gastric juice. However, it should be suspected in cases in which there are other anomalies present.

TREATMENT

Surgical removal of the cyst is the only treatment. When symptoms are present the operative procedure should be performed as early as possible or as soon as it can be tolerated safely. If symptoms are not present and the child is under 2 or 3 years of age a program of close supervision may be instituted and the patient operated on if the mass shows an increase in size. However, thoracotomy should not be deferred after 3 years of age in asymptomatic cases, for the chances of complications are increased and the difficulties of removal greater. Simple aspiration of the cyst is not advisable.

---

[4] Lewis, F. T., and Thyng, F. W.: The Regular Occurrence of Intestinal Diverticula in Embryos of the Pig, Rabbit and Man, Am. J. Anat. 7: 505-519, 1907-1908.

[5] Keith, A.: Human Embryology and Morphology, Baltimore, William Wood & Company, 1933.

Of the 26 cases reported, 9 were diagnosed at autopsy. Surgical intervention was performed in 17 cases and was successful in 10. The youngest patient with successful removal of the cyst was 3 weeks of age when the operation was performed. The surgical procedure of choice is the complete excision of the cyst in one stage. However, the two stage operation of Ladd and Scott is advisable when there is a close attachment of the cyst to the esophagus (to avoid an esophageal fistula) and when the patient's condition is poor. In such instances the first stage consists in freeing the cyst, sewing it to the pleura of the wound and incising it (marsupialization); the second stage consists in either a later excision of the sinus or destruction of the mucosa by gauze packing and curettement, allowing the sinus to become granulated and obliterated. If there is an associated diseased lobe of the lung, it may also be removed.

Of the successful 10 cases, 7 cysts were excised in one stage. Of the 7 unsuccessful cases, 5 patients died as a direct result of the operation and 1 died as a result of a recurring esophagopleural fistula; 1 patient died from pneumonia several months after unsuccessful surgical intervention, death actually being due to nonsurgical causes.

SUMMARY

A case of a congenital intrathoracic mediastinal gastric cyst is reported, and the literature is briefly reviewed. Although intrathoracic mediastinal gastric cysts are rare, they are being discovered with increasing frequency and are amenable to surgical cure.

Clinical Notes, Suggestions and New Instruments

TESTS FOR DETERMINING THE VIABILITY OF STRANGULATED BOWEL

MANUEL E. LICHTENSTEIN, M.D.
Chicago

It is the purpose of this note to call attention to the value of oxygen inhalation in determining the viability of strangulated bowel, lest this simple but useful test be relegated to oblivion. Changes in color and vascular pulsations following the inhalation of pure oxygen have been a test for viability of the bowel for many years, but on inquiry I find that this test is not made use of as frequently as is warranted.

The recognition of the viability of bowel after strangulation in a hernial sac is of importance because thereby an unnecessary resection of the bowel may be avoided and the prognosis may be improved.[1] When the use of warm compresses to improve the circulation is followed by a change in color, restoration of pulsations and return of peristalsis this indication is of therapeutic and diagnostic importance. Failure to respond to this test after a period of time is evidence of nonviability, and resection of the bowel is indicated.

Recently tests have been introduced to determine more promptly the viability of strangulated bowel.[2] Injection of fluorescein intravenously with observation of the affected bowel through a purple light has the advantage of giving an immediate answer to the question. In addition the vasodilator drugs used in peripheral vascular disease have been used to overcome the vasospasm which is frequently associated with strangulation. This test is of diagnostic and therapeutic importance since vasodilators injected locally or systemically improve the circulation by restoring pulsations in the contracted vessels.[2a]

One of the most delicate tests for viability of the bowel is the observance of a change in the color of the bowel concomitant with the inhalation of 100 per cent oxygen. This test may be applied with the patient under local, regional, spinal or general anesthesia. The immediate change of a dusky-colored bowel to a bright pink is an indication that blood is circulating through the wall of the bowel, and viability is assured. Oxygen not only causes the change in color but also aids in the recovery of the damaged segment of bowel. Vascular spasm is diminished or abolished by oxygen, and the pulsations in the involved vessels become fuller and more vigorous. When vascular obstruction or infarction has already ensued following strangulation, the absence of color change and vascular pulsation following the inhalation of oxygen suggests the lack of viability of the bowel. Resection of the involved segment should be performed without further delay.

The dangers incident to a resection of the bowel are not as imposing now as they have been in the past. The use of whole blood transfusions, antibiotics and sulfonamide compounds has to a considerable extent eliminated shock, hemorrhage and infection as causes of failure. Use of parenteral fluids for hydration, mineralization and nutrition and of intestinal intubation for decompression has also improved the patient's prospects for recovery. Satisfactory methods of anesthesia and better technical skill have added to the safety factors in intestinal resection. In the borderline case, in which doubt exists as to the degree of viability, no matter what test is employed the decision to resect the bowel will rest not alone on the results of the test but on the general condition of the bowel. It has been observed[3] that after reduction of a strangulated but viable loop of intestine complete resolution does not always occur. Hemorrhage into the wall of the bowel, edema and deposits of plastic exudate may result in the organization of scar tissue with fibrosis and stenosis, kinking or simple stricture. These changes result in obstruction at a later date and may require short-circuiting operations or resection of the involved segment of bowel.

A segment of bowel that has such doubtful viability that prolonged testing is necessary is not likely to survive, or it may become the seat of serious organic changes. Thus the decision to resect the damaged segment will frequently be influenced by the experience of the surgeon who is viewing the bowel.

After section of the bowel preparatory to anastomosis, doubt may at times arise in the mind of the surgeon concerning the viability of the cut surface to be anastomosed. Here, too, not only will the inhalation of 100 per cent oxygen give a change in color but bright blood will be seen coming from the cut surface. These changes will not be noted when the supply of blood to the cut surface is impaired.

SUMMARY

In the critical case in which the need for differentiation between viable and nonviable bowel is most desirable, clinical judgment has determined the need for resection of the bowel. The use of tests to determine viability have been helpful. The inhalation of 100 per cent oxygen results in a prompt change in color in viable bowel. Other tests are available, but all of them must be viewed in the light of the total damage to the bowel.

PNEUMONIA DUE TO PROTEUS MIRABILIS TREATED WITH PENICILLIN AND STREPTOMYCIN

LOWELL D. SNORF, M.D.
LEONARD SHEPANEK, M.D.
ELIOT E. FOLTZ, M.D.
and
HARRY HARDING, M.D.
Evanston, Ill.

Many cases of dysentery and infections of the urinary tract caused by organisms in the Proteus group have appeared in the literature.[1] These are low grade infections and carry a low mortality rate. Less frequently have otitis media, septicemia and abscess of the brain been due to these organisms.[1] The mortality rate in these cases, however, has been high. The only other reported cases of pulmonary involvement due to Proteus organisms have been 2 cases of pleurisy and 1 case of multiple pulmonary abscesses, all of which were fatal.[2] No previous report of pneumonia due to a Proteus organism could be found.

REPORT OF CASE

History.—A white woman aged 63, married, was admitted to the Evanston Hospital on June 13, 1946 with complaints of chills, vomiting, nausea and diarrhea for one week. In addition she had complained for three years of a severe backache, which was gradually getting worse. Her past and family history were essentially negative.

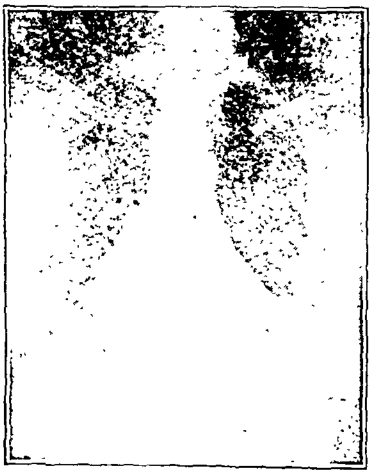

Fig. 1.—Consolidation in the base of the right lung.

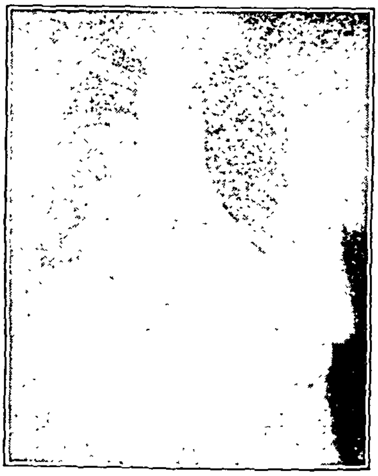

Fig. 2.—Spread of the area of consolidation in the right lung.

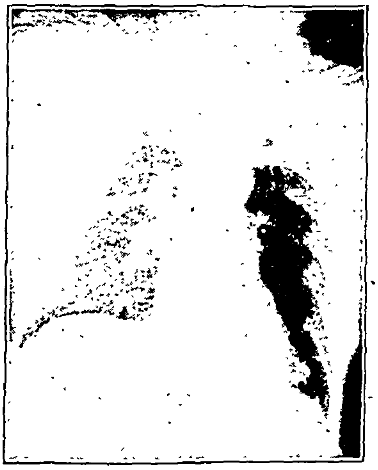

Fig. 3.—New area of consolidation.

Examination.—Physical examination on admission revealed an obese, pasty-complexioned white woman with a temperature of 99.4 F. orally. Her back pain could be exaggerated when active or passive motion of the lower extremities was tried. There was tenderness to palpation in the right upper quadrant of the abdomen but no rebound tenderness. The liver could be felt 1 cm. below the right costal margin with a deep inspiration. The kidneys and spleen were not palpable. There was no detectable fluid in the abdomen. The lungs were clear and resonant. Other physical observations were also normal.

Laboratory Data.—On admission the white blood cell count was 14,800 per cubic millimeter with a preponderance of polymorphonuclear cells and a shift to the left. The sedimentation rate was 100 mm. in one hour. (Westergren). (In the urine were many red and white blood cells.) A cholecystogram demonstrated an inability of the gallbladder to concentrate the dye and a number of round, dense shadows in the region of the gallbladder, which probably represented stones. Roentgen examination of the spine did not show any evidence of disease of the bones or joints. On admission, cultures of the urine and feces were positive for Proteus mirabilis. (In addition the patient's serum in a dilution of 1:320 agglutinated this organism.)

Course of the Illness.—The patient was treated symptomatically and ran a febrile course, which on June 24, eleven days after admission, went up to 103.6 F. orally. The following day clinical evidence of consolidation in the base of the right lung was observed. This was confirmed by a roentgenogram (fig. 1). At this time, because of the pneumonia and because the patient was known to be sensitive to sulfonamide compounds, penicillin therapy was started at the rate of 160,000 units a day.

Blood cultures on July 1 and 3 were positive for P. mirabilis. The patient improved clinically, and the temperature began to approach normal (fig. 4), but on July 9 the patient apparently had an exacerbation of her pneumonia. The temperature spiked to 104 F. orally, and clinical and roentgenologic evidence (fig. 2) showed the consolidation in the right lung to be spreading.

At this point it was felt that since P. mirabilis was found in the urine, feces and blood this organism might well be the etiologic agent for the pneumonia. Because large doses of penicillin have been found to be much more effective than the usual dose in controlling infections due to the coli-aerogenes group,[3] the dosage of penicillin was increased to 1,300,000 units daily. A sputum culture on July 12 was negative for P. mirabilis. The following day, four days after instituting massive penicillin therapy, a blood culture and a sputum culture were positive for this organism. Because blood and sputum cultures remained positive after massive doses of penicillin had been administered, and because, although the patient improved clinically, a new area of consolidation was observed roentgenologically (figs. 3 and 5), a request for streptomycin was made. Treatment with this antibiotic was started on July 23. A total of 10 Gm. was given at the rate of 2 Gm. a day for five days. In vitro tests had demonstrated that for complete inhibition of the growth of this organism a concentration of 0.5 mg. of streptomycin per cubic centimeter or 200 units of penicillin per cubic centimeter was necessary.

Clinical improvement correlated well with the results of the bacteriologic studies. The patient improved gradually from about the fifth day of massive penicillin therapy until her discharge. Cultures of blood, feces and urine were negative from about four days after the start of massive penicillin therapy. (fig. 4). The pneumonia did not completely resolve until the fourth day after the cessation of streptomycin therapy, and it was at this time that the sputum cultures became negative.

[3] Crile, G., Jr., and Fulton, J. R.: Appendicitis, with Emphasis on the Use of Penicillin. U. S. Nav. M. Bull. **45**: 464-474 (Sept.) 1945.

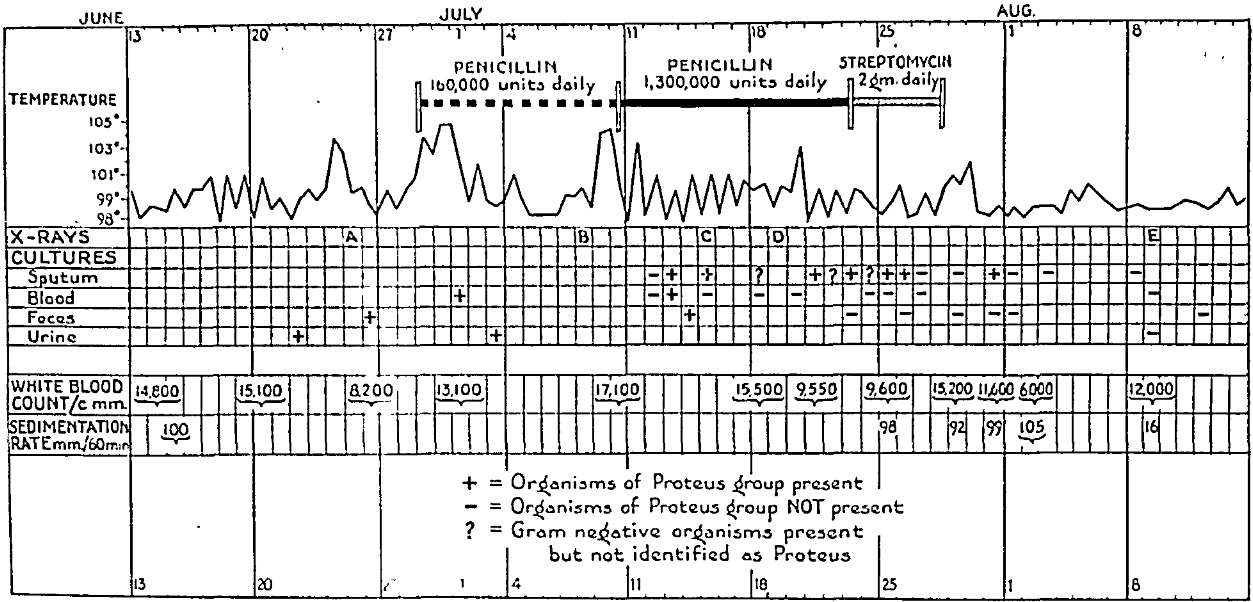

Fig. 4.—Clinical data. Letters A, B, C, D and E (x-rays) correspond to figures 1, 2, 3, 5 and 6.

The patient was discharged from the hospital on August 12 after a hospitalization of sixty days; she was free from all her former complaints. At this time the roentgenogram of the chest had disclosed normal conditions (fig. 6) and the sputum culture had been negative for P. mirabilis for a period of two weeks (fig. 4). Cultures of the blood, feces and urine were likewise negative for this organism. Follow-up studies in the outpatient department for eight months after discharge have shown the patient to remain free of symptoms, to have negative cultures of blood, sputum, urine and feces and to have normal lungs both clinically and roentgenologically.

COMMENT

That the pneumonia in this patient was due to P. mirabilis seems evident from the following: there was a systemic infection with this organism, including a septicemia; the distribution of the consolidation was unusual, and—most important—no pathogenic organism other than P. mirabilis could be found on complete examination of the sputum, and simultaneously with the resolution of the pneumonia this organism disappeared from the sputum.

In the past Proteus infections have been treated most successfully with autogenous vaccines and sulfapyridine.[4] The value of penicillin has been doubtful,[5] but organisms of the Proteus group have been found sensitive to streptomycin.[6] The fact that, in vitro, 200 units of penicillin per cubic centimeter or 0.5 mg. of streptomycin per cubic centimeter were required to inhibit the growth of the organism in this case indicated that this strain of P. mirabilis was decidedly resistant to these agents.[7] For example, the Committee on Chemotherapeutics and Other Agents, National Research Council,[6c] has stated that when as large a dose as 0.6 Gm. of streptomycin is given intravenously, the maximum blood concentration attained is only 26 micrograms per cubic centimeter, far short of the amount required to be effective in this case. Therefore, if these antibiotics exerted any beneficial effect it was most likely in the prevention or control of secondary infections.

It was felt that the backache was independent of involvement of the gallbladder and kidneys, and roentgenograms of the spine were negative. The backache was apparently secondary to obesity and faulty posture and was relieved by rest.

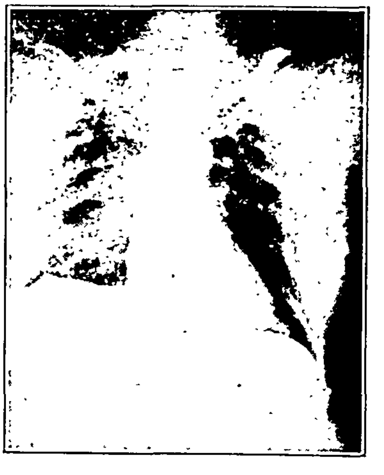

Fig. 5.—Same as figure 3.

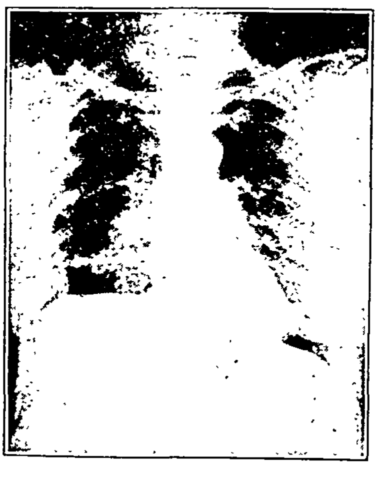

Fig. 6.—Return of lungs to normal.

SUMMARY

A rare case is reported, an infection of the urinary and gastrointestinal tracts, the blood stream and the lungs caused by Proteus mirabilis. The organism was isolated from the feces, urine, blood stream and sputum. Neither penicillin nor streptomycin apparently exerted a direct effect on the primary infection. The patient recovered after an illness of approximately sixty-seven days. We have been unable to find in the literature any other case of pneumonia due to an organism of the Proteus group.

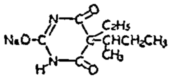
Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., *Secretary.*

BUTABARBITAL SODIUM.—Butisol Sodium-McNeil.—Sodium 5-ethyl-5-sec.-butyl barbituric acid.—Sodium 5-ethyl-5 (1-methyl propyl) barbiturate. — $C_{10}H_{15}N_2O_3Na$.—M. W. 234.23.



Actions and Uses.—Butabarbital sodium produces pharmacologic actions similar to other barbiturates. With average doses the rapidity and duration of its action is intermediate between the fast-acting derivative, pentobarbital, and the longer-acting barbital and phenobarbital. Following oral administration the drug usually exerts initial effects within thirty minutes. Sedation is sustained for approximately five to six hours. It is thus suited for the production of a relatively mild and more continuous depression than can be obtained with the shorter-acting barbituates, yet its action is less prolonged than with barbital or phenobarbital.

Butabarbital sodium is destroyed fairly rapidly in the body, probably in the liver. It is not excreted as such in the urine except with excessive doses and therefore is not contraindicated in the presence of renal disease. Experimental studies indicate it to be essentially nontoxic for the liver. Its therapeutic coefficient is approximately equal to that of pentobarbital and greater than that of phenobarbital.

Butabarbital sodium is used orally as a simple sedative or hypnotic and for preoperative sedation and obstetric hypnosis. Essentially the same clinical precautions to avoid side effects should be observed as for other barbiturates.

Dosage.—Orally: sedative, 8 to 60 mg.; hypnotic, 45 mg. to 0.2 Gm., depending on the purpose and the patient. In general the duration of action is dependent on the size of the dose and the size of the patient. The average oral adult sedative dose is 30 mg.; the average hypnotic dose, 0.1 Gm.

Tests and Standards.—

Butabarbital sodium occurs as a white, bitter-tasting powder. It is soluble in water (1 in 2) and in alcohol (1 in 6.7); practically insoluble in dry ether and in benzene. The pH of a 1 per cent solution is from 9.0 to 10.2.

Dissolve about 0.5 Gm. of butabarbital sodium in 100 cc. of water and acidify the solution with diluted hydrochloric acid. Allow the ethyl sec.-butyl barbituric acid to crystallize from solution, collect it on a filter, wash with water and dry at 100 C.: the crystals melt at 165-168 C.

Incinerate about 0.1 Gm. of butabarbital sodium: the residue responds to tests for sodium carbonate. Dissolve about 0.3 Gm. of butabarbital sodium in 10 cc. of water and divide into two portions; to one portion add 1 cc. of mercuric chloride solution: a white precipitate results, soluble in an excess of ammonia; to the other portion add 5 cc. of silver nitrate solution: a white precipitate results, soluble in an excess of ammonia.

Dissolve about 0.5 Gm. of butabarbital sodium in 5 cc. of sulfuric acid: no more color is produced than that of matching fluid A (U.S.P.) Dissolve about 0.25 Gm. of butabarbital sodium in 25 cc. of water. Add 5 cc. of diluted nitric acid, allow to stand ten minutes and filter. Separate 10 cc. portions of the filtrate yield no greater opalescence on addition of 0.5 cc. of silver nitrate solution than that produced by 0.25 cc. of tenth-normal hydrochloride acid in 50 cc. of water (*chloride*) and no turbidity on addition of 1.0 cc. of barium chloride solution (*sulfate*).

Dissolve 2.0 Gm. of butabarbital sodium in 42 cc. of water and add slowly, with stirring, 8 cc. of normal hydrochloric acid. Filter, rejecting the first 5 cc. of the filtrate: 25 cc. of the filtrate shows no more heavy metals than 30 parts per million (U.S.P.).

Shake 0.5 Gm. of butabarbital sodium with 20 cc. of anhydrous ether for ten minutes, decant the ether through a filter, evaporate the ether in a tared dish, and dry the residue at 100 C.: the weight of the residue does not exceed 3 mg. (*uncombined butabarbital*).

Dry about 1.0 Gm. of butabarbital sodium, accurately weighed, at 100 C. for twenty hours: the loss in weight is not more than 5 per cent.

Dissolve about 0.5 Gm. of butabarbital sodium, accurately weighed, in 10 cc. of water in a separator, add to the solution 15 cc. of diluted hydrochloric acid and extract the liberated butabarbital with eight successive portions of ether, using 25 cc., 20 cc., 20 cc., 10 cc., 10 cc., 10 cc., 10 cc. and 10 cc., respectively. Wash the combined ether extracts with two 5 cc. portions of distilled water. Evaporate the washed ether extract in a tared dish or beaker at a low temperature in a stream of warm air, and dry the residue at 100 C. for two hours: the weight of the residue corresponds to not less than 89 per cent or more than 91 per cent of the sample taken, calculated on the moisture-free basis.

MCNEIL LABORATORIES, INC., PHILADELPHIA

Capsules Butisol Sodium: 0.1 Gm.

Tablets Butisol Sodium: 8 mg., 15 mg. and 50 mg.

Elixir Butisol Sodium: 0.2 Gm. per 30 cc. Butisol Sodium dissolved in a flavored elixir containing 7 per cent alcohol.

U. S. Trademark 378,610.

AMINOPHYLLINE (See New and Nonofficial Remedies, 1947, p. 305).

The following additional dosage form has been accepted:

PREMO PHARMACEUTICAL LABORATORIES, INC., NEW YORK

Suppositories Aminophylline: 0.5 Gm. in a water soluble Carbowax base.

AMPHETAMINE SULFATE (See New and Nonofficial Remedies, 1947, p. 209).

The following additional dosage form has been accepted:

SMITH, KLINE & FRENCH LABORATORIES, PHILADELPHIA

Capsules Benzedrine Sulfate: Amphetamine sulfate, 5 mg.

DIETHYLSTILBESTROL (See New and Nonofficial Remedies, 1947, p. 347).

The following additional dosage form has been accepted:

PREMO PHARMACEUTICAL LABORATORIES, INC., NEW YORK

Diethylstilbestrol (in peanut oil): 0.2 mg. per cc.; 1 cc. ampuls.

ETHINYL ESTRADIOL (See New and Nonofficial Remedies, 1947, p. 352).

The following additional dosage form has been accepted:

SCHERING CORPORATION, BLOOMFIELD, N. J.

Estinyl (Liquid): 125 cc. and 500 cc. bottles. Each 4 cc. contains ethinyl estradiol 0.03 mg. with 20 per cent alcohol.

METHENAMINE (See New and Nonofficial Remedies, 1947, p. 116).

The following dosage form has been accepted:

ABBOTT LABORATORIES, NORTH CHICAGO, ILL.

Tablets Methenamine: 0.3 Gm. and 0.5 Gm.

PENICILLIN (See New and Nonofficial Remedies, 1947 p. 144).

The following additional dosage forms have been accepted:

THE WM. S. MERRELL CO., CINCINNATI

Crystalline Penicillin G Sodium in Oil and Wax 300,000 units per cubic centimeter, 10 cc. vials. Sodium penicillin G suspended in peanut oil, containing 4.8 per cent whit wax, U. S. P.

WYETH INCORPORATED, PHILADELPHIA

Penicillin Calcium in Oil and Wax: 300,000 units pe cubic centimeter, 10 cc. vials. Calcium penicillin suspended i peanut oil containing 4.8 per cent white wax, U. S. P.

STILPALMITATE.—Diethylstilbestrol *di*palmitate.—Th *di*palmitic acid ester of diethylstilbestrol.—$C_{50}H_{80}O_4$.—M. W 745.14. The structural formula of diethylstilbestrol *di*palmitat may be represented as follows:

Actions and Uses.—The actions and uses of stilpalmitate are essentially those of diethylstilbestrol except that the absorption of stilpalmitate is slower. This delay in absorption permits a more prolonged therapeutic effect and is believed to lessen unpleasant side effects.

The contraindications for this preparation are the same as those for all substances with estrogenic action.

Dosage.—Stilpalmitate is given by intramuscular injection only. The usual dose is 5 mg. in terms of the diethylstilbestrol content. As with other estrogens, individual patient response will vary considerably as to rapidity of symptom relief and duration of effect. In the treatment of menopausal symptoms it is suggested that 5 mg. of diethylstilbestrol as the *di*palmitate ester be injected every five to seven days for three to five doses, or until the patient obtains satisfactory relief. Treatment is then interrupted until symptoms recur. At that time injections may be repeated at five to seven day intervals until symptoms are again relieved. The duration of symptomatic relief between dosage periods will vary from four to twelve weeks.

Lactation may be suppressed during the puerperium by the injection of 10 mg. of diethylstilbestrol as the *di*palmitate ester on the day of delivery and 5 mg. on the first and second postpartum days.

Ampuls must be immersed in hot water to dissolve the stilpalmitate, which is insoluble at room temperature. The drug will remain in solution at body temperature.

Tests and Standards.—

Stilpalmitate occurs as a white to yellowish, odorless, waxy, crystalline powder. It is practically insoluble in water; slightly soluble in alcohol; sparingly soluble in fatty oils at room temperature, but dissolves more freely on warming; soluble in ether and in chloroform. It melts between 81 and 85 C.

Dry about 0.25 Gm. of stilpalmitate over concentrated sulfuric acid in a vacuum desiccator for twenty-four hours: the loss in weight is not more than 0.1 per cent.

Transfer about 13.85 *mg. of diethylstilbestrol di*palmitate, accurately weighed, to a 125 cc. Erlenmeyer flask. Add 10 cc. of alcohol and 3 drops of concentrated sulfuric acid. Hydrolyze in a boiling water bath under a reflux condenser for two hours. Transfer the solution quantitatively to a 100 cc. volumetric flask and make up to volume with alcohol. To 5 cc. of the hydrolyzed solution in a 100 cc. volumetric flask, add 5 cc. of distilled water, 2 cc of diluted hydrochloric acid, 4 cc. of molybdophosphotungstate test solution (U.S.P.) and 50 cc. of distilled water. Allow to stand for ten minutes, then add 10 cc. of a 25 per cent aqueous solution of anhydrous sodium carbonate; dilute to exactly 100 cc., *mix* well and allow to stand for forty-five minutes. Filter the solution through a dry filter, rejecting the first portion of the filtrate. Treat a 5 cc. portion of diethylstilbestrol standard solution (10 mg. of diethylstilbestrol U. S. P. Reference Standard in alcohol to make 200 cc.) with the same quantities of reagents and in the same manner as the sample being tested. Treat a 5 cc. portion of alcohol in the same manner. This constitutes the blank. Determine the optical density of the solutions in a suitable photoelectric colorimeter or spectrophotometer at a wavelength of about 5,500 angstroms, using the blank as 100 per cent transmission. Calculate the quantity of diethylstilbestrol represented in the unknown: the diethylstilbestrol content is not less than 34.5 per cent nor more than 37.5 per cent.

Abbott Laboratories, North Chicago, Ill.

Stilpalmitate in Oil: 1 cc. ampuls. Ampuls containing 7 mg. of stilpalmitate per cc. or 14 mg. of stilpalmitate per cc., dissolved in peanut oil.

BENZESTROL (See New and Nonofficial Remedies, 1947, p. 347).

The following additional dosage form has been accepted:

Schieffelin & Co., New York

Benzestrol Elixir: 473 cc. bottles. Each 4 cc. contains benzestrol 2 mg. in a sweetened aromatic elixir containing alcohol 25 per cent.

PARENAMINE (See New and Nonofficial Remedies, 1947, p. 383).

The following dosage form has been accepted:

Frederick Stearns & Co., Detroit

Parenamine 15% Solution: Bottles of 100 cc. contain 15 Gm. of casein hydrolysate, consisting essentially of amino acids, per hundred cubic centimeters of solution.

ETHYLSTIBAMINE (See New and Nonofficial Remedies, 1947, p. 154).

The following dosage form has been accepted:

Winthrop Chemical Co., Inc., New York

Neostibosan: 0.3 Gm. ampuls.

U. S. patent 1,988,632. U. S. trademark 400,894.

PYRIDOXINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1947, p. 516).

The following dosage form has been accepted:

U. S. Vitamin Corporation, New York

Solution Pyridoxine Hydrochloride: 50 mg. per cc., 10 cc. vials. Preserved with 0.5 per cent chlorobutanol.

DIGITOXIN (See New and Nonofficial Remedies, 1947, p. 250).

The following dosage forms have been accepted:

Wyeth Incorporated, Philadelphia

Purodigin Injection: 1 cc. ampuls. Each cubic centimeter contains 0.2 mg. of digitoxin *in 40 per cent alcohol solution.*

Tablets Purodigin: 0.1 mg. and 0.2 mg.

U. S. trademark 411,271.

ESTROGENIC SUBSTANCES (Water Insoluble) (See New and Nonofficial Remedies, 1947, p. 343).

The following dosage forms have been accepted:

Endo Products, Inc., Richmond Hill, N. Y.

Solution Estromone in Oil: 1 cc. ampuls and 10 and 25 cc. vials. Each cubic centimeter contains estrogenic substances equivalent to 2,000, 5,000, 10,000 or 20,000 international units of estrone in sesame oil. The 10 cc. and 25 cc. vials contain 0.5 per cent chlorobutanol as preservative.

U. S. trademark 345,724.

Premo Pharmaceutical Laboratories, Inc., New York

Solution of Estrogenic Substances: 1 cc. ampuls and 10 cc., 20 cc. and 30 cc. vials, containing the equivalent of 10,000 international units and 20,000 international units per cubic centimeter and 10 cc., 20 cc. and 30 cc. vials containing the equivalent of 25,000 international units per cubic centimeter of estrone in sesame oil with 0.5 per cent chlorobutanol as preservative.

Warren-Teed Products Company, Columbus, Ohio

Solution Estrovarin (in Oil): 15 cc. vials. Each cubic centimeter contains estrogenic substances equivalent to 10,000 international units of estrone in sesame oil, with chlorobutanol 0.5 per cent as a preservative.

DIPHENHYDRAMINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1947, p. 19).

The following dosage form has been accepted:

Parke, Davis & Co., Detroit

Kapseals Benadryl Hydrochloride: 50 mg.

Elixir Benadryl Hydrochloride: 473 cc. Each hundred cubic centimeters contains benadryl hydrochloride 0.25 Gm. in an elixir containing alcohol, glycerin and water, with sugar, flavoring oils and added color. Each 4 cc. contains 10 mg. of benadryl hydrochloride.

U. S. trademark 416,252.

STIBAMINE GLUCOSIDE (See New and Nonofficial Remedies, 1947, p. 155).

The following dosage form has been accepted:

Burroughs Wellcome & Co., New York

Neostam Stibamine Glucoside: 0.1, 0.2 and 0.5 Gm. vials. Each vial contains the stated quantity of stibamine glucoside hermetically sealed under nitrogen to preserve stability.

ASCORBIC ACID (See New and Nonofficial Remedies, 1947, p. 517).

The following dosage form has been accepted:

U. S. Vitamin Corporation, New York

Tablets Ascorbic Acid: 25 mg., 50 mg. and 100 mg.

MENADIONE (See New and Nonofficial Remedies, 1947, p. 533).

The following dosage forms have been accepted:

U. S. Vitamin Corporation, New York

Solution Menadione in Oil, 1 mg. per cc.: 1 cc. ampuls. Each cubic centimeter contains 1 mg. of menadione in corn oil.

Capsules Menadione: 1 mg. and 2 mg.

RIBOFLAVIN (See New and Nonofficial Remedies, 1947, p. 511).

The following dosage form has been accepted:

U. S. Vitamin Corporation, New York

Tablets Riboflavin: 1 mg. and 5 mg.

OLEOVITAMIN A (See New and Nonofficial Remedies, 1947, p. 502).

The following dosage form has been accepted:

Premo Pharmaceutical Laboratories, Inc., New York

Vitamin A Capsules: Each capsule contains 25,000 U. S. P. units of vitamin A derived from natural fish liver oils.

NICOTINIC ACID (See New and Nonofficial Remedies, 1947, p. 512).

The following dosage form has been accepted:

U. S. Vitamin Corporation, New York

Tablets Niacin: 25 mg., 50 mg. and 100 mg.

SATURDAY, SEPTEMBER 27, 1947

PROGRESS OF BREAD AND FLOUR ENRICHMENT

The enrichment of white bread and flour was started in May 1941 in about 30 per cent of the nation's output as a voluntary practice of bakers and millers. By late 1942 the percentage affected had risen to 75 or 80. However, the fraction not enriched included most of the low priced flours, destined for low income groups which stood in greatest need of this nutritional benefit.

South Carolina first sought to meet this situation by compulsory legislation which became effective Aug. 1, 1942. Five other Southern states followed this example in 1943 and 1944. The movement spread west and north in 1945 to include twelve more states. During 1946-1947 the total has risen to twenty-one states.[1] Perhaps it would be much higher but for the vigorous opposition of the American Dry Milk Institute. The opposition has been predicated on the assumption that enrichment encourages omission of nonfat milk solids from bread. However, convincing evidence has not been submitted to indicate that this is true.

The proponents of enrichment on the Food and Nutrition Board of the National Research Council all have been earnest advocates of the use of milk in bread. They believe that the war shortages of milk solids due to exports to Britain account for whatever reduction occurred in the use of milk in bread. Bakers use milk solids in bread to improve texture and delay staling as well as for nutritional values. Bakery use constitutes much the most important outlet for nonfat milk solids. It is questionable wisdom for the American Dry Milk Institute to oppose enrichment legislation, thus offending their largest customers and most nutritionists.

Nonfat milk solids as well as yeast, wheat germ, salt, fat and sugar are permissible ingredients in all bread, both enriched and unenriched. The practice of using nonfat milk solids in loaf breads was already well established before enrichment began, and it continues unabated. Little loaf bread is made without milk solids, and the total milk solids used in enriched bread is probably five times that used in unenriched bread today. It is therefore absurd to say, as has been said, that the product of the farms is being displaced by the product of the chemical factory. So-called water breads, typified by Vienna and Italian style breads, do not employ milk solids, as they would lose their characteristics were milk to be incorporated. However, breads of this type represent only a small proportion of commercial bread.

The addition of pure vitamins to bread and flour rather than addition of milk, corn germ, yeast or other natural carriers of vitamins does not affect the baking qualities of flour or the taste of bread. The natural products when added to flour affect both taste and baking qualities, and their compulsory addition, if the product was not acceptable to the purchaser, might wreck a program which depended for success on acceptance by the public.

Certain opponents of the enrichment program, some affiliates of commercial enterprises with interests supposedly in conflict with the program, have circulated misinformation which has gone so far as to suggest that R. R. Williams, who first synthesized thiamine, has been motivated by personal gain in encouraging the enrichment program; also that through his opposition the Food and Nutrition Board of the National Research Council has been dissuaded from considering the greater advantage of enriching flour and bread with corn germ or the like. Nothing could be further from the truth. The program had its beginning in the Council on Foods and Nutrition of the American Medical Association, and Dr. Williams had no part in the deliberations of that Council. The membership of the Food and Nutrition Board is such as to preclude the possibility of any such influence on its judgments, and the royalties for the patents on thiamine synthesis are deeded by Dr. Williams to the Research Corporation to be used exclusively for research.

The enrichment of bread program was aided by a war food order requiring it in January 1943. However, there has been little decline in enrichment of bread since the termination of the order in October 1946. The practice of enriching with vitamins remains popular in both the baking and the milling industries, though less so in some of the smaller local bakeries and mills. What then is the purpose or need of extending enrichment legislation?

The record shows that legislation, especially in the South, was important in extending enrichment to cheaper flours and therefore to the needier low income groups. Enrichment which applied only to the bread of the middle and upper classes would benefit the milling and baking industries but fail to achieve high values in public health. Furthermore, legislation when supported by public opinion provides insurance against neglect of the practice in times of greatest need. The value of compulsory enrichment of bread and flour will be conspicuous in case of a business recession. Under the highly competitive conditions characteristic of such a period, the cost cutting incentive would otherwise lead to serious curtailment at the time when low income people were turning to cereal products as a measure of economy.

---

[1] Enrichment legislation has been passed by Alabama, Arkansas, Georgia, Indiana, Kansas, Kentucky, Louisiana, Maine, Mississippi, New Hampshire, New Jersey, New York, North Carolina, North Dakota, Oklahoma, South Carolina, South Dakota, Texas, Washington, West Virginia and Wyoming.

There is an increasing demand for "proof" that enrichment is benefiting public health. Such proof can come only from long term experience and observation of human nutrition. Animal experiments with bread as the principal or sole article of food depart from human practices so far as to invalidate tests. Therefore judgment must be based on the integrated experience of leading students of the intricate field of nutrition. This continues strongly to support the enrichment program.

EXPENDITURES FOR MEDICAL CARE

Recently Frank G. Dickinson, Ph.D., Director of the Bureau of Medical Economic Research of the American Medical Association has made available a twelve-page pamphlet, replete with charts and tables, which presents in detail the calculations and the source of each figure related to the costs of medical care. Since 1940, despite increasing demands for medical care, the proportion of national income spent for medical services has, according to these figures, actually declined. A preview of this study was presented by Dr. Dickinson in the Bureau's exhibit at the Centennial Session of the American Medical Association in Atlantic City. Completion has been made possible by the recent publication of data relative to national income by the U. S. Department of Commerce. The conclusions fall into two categories; what is happening to costs of medical care as a whole, and what is happening to the relative shares of the medical care dollar.

Costs of medical care as a whole tend to move countercyclically; in a depression such costs comprise a larger share of total consumer expenditures and national income than they do in prosperous times. In a period such as the present, the trend is toward more furious inflation and lower relative expenditures for medical care. This is borne out by Dr. Dickinson's figures—medical care took 4.4 per cent of total consumer expenditures in 1932 and 1933, then the share trended downward to 3.9 per cent in 1946. Necessities always loom more important in depression; luxuries, in prosperity. But all evidence indicates that, case for case, medical care costs more each year—particularly where hospital care is concerned. Thus the decline in relative importance of medical care expenditures has occurred in spite of climbing costs of specific treatments and an overall increase in demand for medical services arising from the aging population, the high birth rate and popular education in health, which lessens fear of hospitals.

The declining percentage of income expended on medical care is paralleled by increasing proportions spent on alcoholic beverages, recreation, personal care and jewelry; these items in the budget were selected by Dr. Dickinson not for moral reasons but for comparability in the size of total expenditures.

Physicians will be interested to learn that their share of the medical care dollar has declined from 32 cents in 1929 to 27 cents in 1945. Part of this decline may have been caused by the absence of those physicians who were in the armed forces during 1945. The gap was filled chiefly by increases in the share of the medical care dollar spent for drugs.

FATAL POLIOMYELITIS IN A LABORATORY TECHNICIAN

Accidental infection with poliomyelitis virus contracted in the laboratory has been reported only twice. The first case[1] was that of a woman who had been preparing virus suspension from the tissue of monkeys infected with strains recently isolated from human sources. Recently Wenner and Paul[2] reported the case of a young male technician in the Yale Poliomyelitis Study Unit, who had been trained to assist in the preparation of virus suspensions and centrifugation prior to the inoculation of experimental animals. New Haven had relatively few cases of poliomyelitis during July and August, 1945; this technician had not been out of the city during that period. Two weeks before admission to the hospital his wrist had been deeply scratched by an uninoculated monkey. Virus may have contaminated his hands subsequent to this injury. He was brought to the hospital on Aug. 24, 1945 and died two days later on the ninth day of his disease. Specimens of various tissues were carefully removed at necropsy for virus studies, using the technic of Sabin and Ward.[3] Sterile instruments were used for each different tissue, and all material was kept frozen until tested several weeks later. Poliomyelitis virus was thus detected in the pharyngeal material, in the pons, medulla and spinal cord, axillary lymph nodes on the right side, mesenteric lymph nodes and in the duodenal wall. Virus was not found in the axillary lymph nodes on the left.

This patient had been exposed in the laboratory to strains of virus recently isolated from human beings; that was also the situation in the only other reported case of laboratory infection with poliomyelitis virus.

Wenner and Paul emphasize the danger of exposing technicians to strains of poliomyelitis virus recently isolated from human sources. They believe that manual work with this virus is more dangerous than work with

patients ill with poliomyelitis. The case at Yale also suggests the possibility of acquiring poliomyelitis by the cutaneous route. The presence of poliomyelitis virus in the axillary lymph nodes on the right side, as opposed to those on the left, may be significant in view of the deep-scratch which the patient sustained on his right wrist a short time before his fatal illness.

Knowledge of the viruses is still in an early experimental stage. Enough is known to indicate the hazard associated with study of the viruses because of their extraordinary virulence under favorable circumstances.

Current Comment

CHEMICAL CARCINOGENESIS

A remarkable issue of the *British Medical Bulletin* (4:309 [No. 5-6] 1947) is devoted to chemical carcinogenesis. Eighteen papers by different authors from eleven centers review the problems and the results of research supported in part by the British Empire Cancer Campaign over more than twenty years. Many aspects of chemical carcinogenesis, in which the British did much of the pioneer work, are expertly discussed. Each paper is worthy of study. Some physicians should find the papers on skin, bladder, liver and arsenic-induced cancers of special interest. Others will find special appeal in the discussions on carcinogenic substances in human tissues, the role of estrogens in carcinogenesis, carcinogenic action of heated fats and lipids, chemotherapy and other subjects. Despite present accomplishments, more remains to be done, and this line of investigation offers the possibility, at its maximum, of doing much to help solve the causes of cancer.

PYRUVIC ACID AND THE LIVER

The suggestion of the intermediary position of the liver in the lactic acid-carbohydrate cycle was made in 1928.[1] To the well known ability of this organ to form glycogen from sugar, amino acids and fat was thus added the capacity to transform lactic acid to glycogen. The close association of lactic acid to pyruvic acid in the metabolism of carbohydrate suggested studies[2] on the relation of several organs to the transformation of pyruvic acid in the organism. The level of pyruvate was elevated in some of the laboratory animals by restricting the vitamin B_1 in the diet. Simultaneous analyses of blood from the femoral artery and vein and from the hepatic and portal veins were carried out for pyruvic acid, lactic acid and glucose. In both normal and thiamine deficient animals the liver withdraws lactate and pyruvate from the blood and returns glucose to the systemic circulation. The intestine contributes pyruvate to the portal vein irrespective of the adequacy of the thiamine of the diet, and the same situation obtained with reference to the muscle and lactic acid. Thus the liver can transform pyruvate to glucose in much the same way as it does with lactate, an observation in general harmony with current physiologic chemical views of carbohydrate metabolism.

BOECK'S SARCOID

Boeck[1] originally described sarcoid as a disease that is characterized by multiple nodular lesions of the skin of unknown cause associated with superficial lymph node enlargements. This conception has since been extended to include similar if not identical changes in practically every organ in the body, among them the eye, nose and accessory sinuses, lungs, deep as well as superficial lymph nodes, liver, kidneys, spleen, heart, pituitary, testicle, prostate and bones. Histologically the changes bear a noteworthy resemblance to those of tuberculosis. In many cases the giant cells in the tubercle-like formations of sarcoid contain deposits of calcific material such as are seldom if ever encountered in the giant cells of tuberculosis. However, giant cells are not always present in the histologic lesions of sarcoid and, when present, do not always contain calcific inclusions. Nevertheless, discussion concerning the nature of the disease is focalized almost exclusively on whether sarcoid is or is not a form of tuberculosis. In 1910 Kyrle[2] and Morawetz[3] independently and in 1914 Sweitzer[4] injected emulsified sarcoid tissue into guinea pigs and produced lesions which were histologically indistinguishable from those of tuberculosis. Sometimes the reactions in guinea pigs were prompt; in one animal no reaction was observed until ten months after injection. The validity of these experiments has since been challenged because no precautions were taken to prevent cage infections. In 1941 Longcope[5] reported that "from inoculation of tissue into guinea pigs, rabbits and pigeons we have not obtained any evidence to support the view that the disease is caused by human, bovine or avian tubercle bacilli." In sarcoid it has been shown by various investigators that plasma proteins are increased, especially the globulin fraction. However, Seibert[6] and her co-workers have shown that increase in the globulin fraction occurs also in tuberculosis. The view that Boeck's sarcoid is a form of tuberculosis seems to rest solely on microscopic differences in the giant cells occasioned by the deposit in them of calcified material in sarcoid and its absence in the giant cells of tubercles. Since the results of animal inoculations are unsatisfactory or even contradictory, experiments of this sort should be repeated with due regard for the prevention of cage infections and for delayed reactions in experimental animals.

ORGANIZATION SECTION

Official Notes

THE INTERIM SESSION OF THE AMERICAN MEDICAL ASSOCIATION

After careful investigation of the availability of accommodations for a midwinter (supplemental) session of the American Medical Association in the short time at its disposal, the Board of Trustees selected Cleveland as the place of that session, since the accommodations for meeting places and for sleeping rooms seemed to be adequate and a convenient time seemed to be open. The midwinter session will therefore be held in Cleveland, Jan. 5 to 8, 1948, the first two days being devoted to a session of the House of Delegates and January 7 and 8 to General Scientific Meetings devoted exclusively to the general practitioner.

The Scientific Meetings, the Scientific Exhibit and the Technical Exposition will be housed in the Cleveland Auditorium, but the place of meeting for the House of Delegates has not yet been selected. The Council on Scientific Assembly, in cooperation with the Board of Trustees, will prepare the program for the Scientific Meetings.

Information concerning hotel reservations will be published as soon as arrangements concerning this matter have been completed.

Washington Letter

(From a Special Correspondent)

Sept. 25, 1947.

Varied Comment on Medical Service for Veterans

Despite VFW criticism of the Veterans Administration Medical Service, General Bradley, Veterans Administrator, has been rated by press critics as "the most able and effective appointment Mr. Truman has made." Newspapers which have expressed support of the view of General Dwight D. Eisenhower, Army Chief of Staff, that General Bradley be his successor, contend that he is entitled to the promotion because of his brilliant record as a soldier and as head of the Veterans Administration. Typical comment: "The wrong man as administrator of veterans affairs could easily have shattered America in a few short months. But instead, General Bradley has held the confidence of the veterans, the civilian population and Congress through a period that undoubtedly has been as trying to him as anything that ever happened during the war with Hitler."

James F. O'Neil, new national commander of the American Legion, among other things criticized hospitalization for veterans, but conceded that the provision of hospital beds for veterans had shown signs of progress but was "not satisfactory." The medical service of the Veterans Administration was highly praised by Dr. Charles B. Puestow, clinical professor of surgery, University of Illinois College of Medicine. He said that the finest type of medical care is now available to veterans under the reorganized medical program of the agency, which he said was the result of work by General Bradley, Dr. Paul R. Hawley, medical director, and Dr. Paul B. Magnusson. Dr. Puestow said the reorganization places the care of veterans directly under the supervision of the great United States medical schools, of which fifty-six are operating medical care in sixty-two veterans' hospitals. He also said that patients now get virtually immediate surgical care, where formerly they had to go on waiting lists.

Reports Improvement in Artificial Limbs

Robert S. Allen, chairman, Prosthetics Advisory Committee of the Veterans Administration, told a news conference that three new artificial arms, which are being made available to some 4,500 veterans this week, represent decided improvements in artificial arms. Developed by Northrup Aircraft Company, A. J. Hosmer Corporation and the Navy, distribution of the new arms has been held up since their invention two years ago to permit them to be submitted to extensive tests. Features of the new arms are said to be their light weight, special elbow controls (which can be locked in any position) and increased maneuverability. The limbs were developed with funds supplied by the Veterans Administration and the Army, and contracts for manufacture were let through the Artificial Limbs Committee of the National Research Council.

Deputy Chief Deplores "Assembly-Line Medicine"

Rear Admiral H. L. Pugh, Deputy Surgeon General of the Navy, said at the opening of George Washington University Medical School's academic year that there is an "assembly-line system of medicine" in America today. He said that too little attention is now paid to "the personal patient-physician relationship." He advised students to "look at a sick person as an individual rather than as a case." He deplored the paucity of studies in the humanities by medical students and declared that "the course in medicine is highly technical and produces medical men who are scientists and technicians but not scholars." He charged that the high cost of a medical education "tends to limit the candidates to a certain economic group."

Committee Advocates Training Physicians in Radiation Medicine

The Atomic Energy Commission's advisory committee for biology and medicine has emphasized the urgent need for more physicians with specialized training in the new field of "radiation medicine." The Committee devoted most of its initial session to discussion of personnel needs, which are regarded as serious. Members urged that steps be taken at once to train more young scientists in "atomic biology," the mysterious effect of nuclear radiation on the human body.

Surgical Operations to be Televised at Washington

Surgical operations will be televised from Georgetown University and Doctors hospitals during the eighteenth annual scientific assembly of the District of Columbia Medical Society, October 6, 7 and 8, in Washington, according to Dr. Robert H. Groh, assembly chairman. The telecasts will record operating procedure rather than technical aspects of operations.

Council on Medical Service

SOUTHEASTERN REGIONAL CONFERENCE

The Council on Medical Service is sponsoring a regional conference to be held in the Academy of Medicine Building, 875 West Peachtree Street, N. E., Atlanta, Ga., Oct. 6, 1947. Registration begins promptly at 8:30 Wednesday morning.

Dr. Walter B. Martin, member of the Council on Medical Service, is chairman of the conference; Dr. Steve P. Kenyon, president, Medical Association of Georgia, will welcome those present, and Dr. Harrison H. Shoulders, Past President of the American Medical Association, will talk on "Services the American Medical Association Can Render State Medical Societies."

Rural Health Problems in The South is the keynote. During the conference tribute will be paid to the late Dr. Charles W. Roberts for his long service in medical organizational activities. At the time of his death Dr. Roberts was a member of the Board of Trustees of the American Medical Association and was active in the Medical Association of Georgia.

The Hon. M. E. Thompson, governor of Georgia, will speak. Another topic will be "American Medicine's Rural Health Program," by Dr. F. S. Crockett, chairman, Committee on Rural

Medical Service of the American Medical Association. Dr. Crockett's talk will be discussed by Drs. J. Paul Jones and H. B. Mulholland, members of this committee.

The morning session will be followed by an open forum on "How Shall We Provide Medical Care For All The People?" After the afternoon session the rural health committees of the various states will hold a dinner meeting to discuss, in more detail, the rural health problems.

The eight southeastern state medical societies participating in the conference are those of Alabama, Georgia, Florida, Mississippi, North Carolina, South Carolina, Tennessee and Virginia. All physicians in the area are invited to attend. Dr. Edgar H. Greene, 478 Peachtree Street, N. E., Atlanta, Ga., is chairman of the arrangements committee, and all correspondence should be addressed to him. For room accommodations write to the following hotels: Atlanta Biltmore, Henry Grady, Piedmont, Georgian Terrace, Robert Fulton, Ansley, Atlantan.

Local Committee on Arrangements:

Steve P. Kenyon, M.D., president, Medical Association of Georgia, Dawson.

Edgar H. Greene, M.D., president-elect, Medical Association of Georgia, Atlanta.

Allen H. Bunce, M.D., delegate to the American Medical Association from Georgia, Atlanta.

B. H. Minchew, M.D., general chairman, State Committee on Prepayment Medical Plans for Georgia, Waycross.

Edgar D. Shanks, M.D., secretary-treasurer, Medical Association of Georgia, Atlanta.

O. H. Weaver, M.D., delegate to the American Medical Association from Georgia, Macon.

Spencer A. Kirkland, M.D., chairman, State Committee on Public Policy and Legislation, Atlanta.

SOUTHERN REGIONAL CONFERENCE

The Southern Regional Conference of the Council on Medical Service will be held at the Roosevelt Hotel in New Orleans, October 23-24. Participating with the Council in this conference are the Council on Industrial Health and the Committee on Rural Medical Service of the American Medical Association and the following state medical associations: Alabama, Arkansas, Louisiana, Mississippi, Oklahoma, Tennessee and Texas.

Employing a somewhat different pattern than that used in ast regional conferences, the Council has divided the New rleans meeting into a series of round-table discussions, each directed by a moderator, with all present invited and expected to take part. Dr. James R. McVay, chairman, Council on Medical Service, will be in charge of this conference, which will begin at 9:30 a. m. Thursday. The address of welcome will be given jointly by Drs. Gilbert C. Anderson, president, Louisiana State Medical Society, and H. Ashton Thomas, president, Orleans Parish Medical Society.

Dr. McVay will outline the purpose of the conference and then introduce Dr. George F. Lull, Secretary and General Manager of the American Medical Association, who will talk on "Liaison Between the American Medical Association and the Component Medical Societies."

The round-table discussions start at 10:30 a. m. Thursday. For the first subject, "What Is Good Medical Society Public Relations?" Mr. Henry S. Johnson, director of public relations, Medical Society of Virginia, will act as moderator. During luncheon on Thursday Dr. Joseph S. Lawrence, director, Washington office of the Council on Medical Service, will present "The Washington Legislative Picture." Thursday afternoon will be devoted to a round-table analysis of "Prepayment Medical and Surgical Care Plan Problems." Dr. Charles R. Henry, chairman, Committee on Medical Service and Public Relations, Arkansas Medical Society, will act as moderator.

The round-table discussion Friday morning will be on "Health Problems of the Workers of the South." Dr. Stanley J. Seeger, former chairman, Council on Industrial Health of the American Medical Association, will act as moderator. Panel discussants will include five physicians familiar with the industrial health problems of the Southern states. On Friday afternoon the round-table will be on "Rural Health Problems of the South." Dr. J. Paul Jones, member of the Committee on Rural Medical Service of the American Medical Association, will act as moderator.

Each of the moderators will be assisted by five discussants, who will present fifteen minute talks and make up the various panels. The last hour of each session will be devoted to questions and answers, and all present will be invited to participate. All physicians in the area are welcome and invited to attend.

Mr. Frank Lais, executive director of the Council on Medical Service and Public Relations of the Louisiana State Medical Society, is acting as the secretary for the local committee on arrangements, and all communications should be addressed to him in care of the Louisiana State Medical Society, 1430 Tulane Avenue, New Orleans 13.

Coming Medical Meetings

Conference of State Medical Society Secretaries and Editors, Chicago, A.M.A. Headquarters, Nov. 7-8. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

American Academy of Neurological Surgery, Colorado Springs, Broadmoor Hotel, Oct. 9-11. Dr. T. C. Erickson, 1300 University Ave., Madison 5, Wis., Secretary.

American Academy of Ophthalmology and Otolaryngology, Chicago, Palmer House, Oct. 12-17. Dr. W. L. Benedict, 102 Second Ave. S.W., Rochester, Minn., Secretary.

American Anti-Arthritis Association, Del Mar, Calif., Oct. 4-5. Dr. Robert T. Pottenger, 65 N. Madison Ave., Pasadena, Calif., Secretary.

American Clinical and Climatological Association, Colorado Springs, Oct 13-15. Dr. James Bordley III, Johns Hopkins Hospital, Baltimore 5, Secretary.

American Public Health Association, Atlantic City, Oct. 6-10. Dr. Reginald M. Atwater, 1790 Broadway, New York 19, Executive Secretary.

American Society for the Study of Arteriosclerosis, Chicago, Hotel Knickerbocker, Nov. 2-3. Dr. O. J. Pollak, Wilmington General Hospital, Wilmington 14, Delaware, Secretary.

American Society of Clinical Pathologists, Chicago, Drake Hotel, Oct. 28-30. Dr. A. S. Giordano, 531 N. Main St., South Bend, Ind., Secretary.

Association of American Medical Colleges, Sun Valley, Idaho, Oct. 27-29. Dr. Fred C. Zapffe, 5 S. Wabash Ave., Chicago, Secretary.

Association of Medical Illustrators, New Orleans, Sept. 29-Oct. 2. Miss Muriel McLatchie, Massachusetts General Hospital, Boston, Secretary.

Association of Military Surgeons of the United States, Boston, Nov. 13-15. Col. James M. Phalen, Army Medical Museum, Washington 25, D. C., Secretary.

Central Neuropsychiatric Association, Galveston, Texas, Oct. 17-18. Dr. William C. Menninger, 3617 W. Sixth Ave., Topeka, Kans., Secretary

Delaware, Medical Society of, Wilmington, Oct. 13-15. Dr. John F. Hynes, Memorial Hospital, Wilmington, Secretary.

District of Columbia, Medical Society of the, Washington, Hotel Statler, Oct. 6-8. Mr. Theodore Wiprud, 1718 M Street N.W., Washington 6, Secretary.

Indiana State Medical Association, French Lick, Oct. 28-30. Mr. Ray E. Smith, 23 E. Ohio St., Indianapolis 4, Executive Secretary.

International College of Surgeons, U. S. Chapter, Chicago, Palmer House Sept. 29-Oct. 2. Dr. Louis J. Gariepy, 16401 Grand River Ave., Detroit 27, Secretary.

Inter-State Postgraduate Medical Association of North America, St. Louis, Public Auditorium, Oct. 14-17. Dr. Tom B. Throckmorton, 406 Sixth Ave., Des Moines, Iowa, Secretary.

Kansas City Southwest Clinical Society, Kansas City, Mo., Municipal Auditorium, Oct. 6-9. Mr. E. Leas Clower, 630 Shukert Bldg., Kansas City 6, Executive Secretary.

Kentucky State Medical Association, Louisville, Sept. 29-Oct 2 Dr P. E. Blackerby, 620 S. Third St. Louisville 2, Secretary.

Michigan State Medical Society, Grand Rapids, Pantlind Hotel, Sept. 23-26. Dr. L. Fernald Foster, 2020 Olds Tower, Lansing 8, Secretary.

Mississippi Valley Medical Society, Burlington, Iowa, Oct. 1-3. Dr Harold Swanberg, 510 Maine St., Quincy, Ill., Secretary.

New England Postgraduate Assembly, Boston, Copley-Plaza Hotel, Oct. 29-31. Dr. Leroy E. Parkins, 8 Fenway, Boston 15, Chairman.

New York State Association of Public Health Laboratories, Albany, Nov. 7. Miss M. B. Kirkbride, New Scotland Ave., Albany 1, Secretary.

Oklahoma City Clinical Society, Oklahoma City, Biltmore Hotel, Oct. 27-30. Dr. Elmer R. Musick, 512 Medical Arts Bldg., Oklahoma City, Director of Clinics.

Omaha Mid-West Clinical Society, Omaha, Oct. 27-31. Dr. John M. Thomas, 1031 Medical Arts Bldg., Omaha 2, Secretary and Director of Clinics.

Southern Psychiatric Association, Birmingham, Ala., Oct. 13-14. Dr. Newdigate M. Owensby, 384 Peachtree St. N.E., Atlanta, Ga., Secretary.

Southwestern Medical Association, Phoenix, Ariz., Hotel Westward Ho, Nov. 6-8. Dr. Louis W. Breck, 116 Mills St., El Paso, Texas, Secretary.

Vermont State Medical Society, Burlington, Hotel Vermont, Oct. 1-3 Dr. Theodore H. Harwood, 128 Merchants Row, Rutland, Secretary.

Virginia, Medical Society of, Roanoke, Oct. 13-15. Miss Agnes V. Edwards, 1200 E. Clay St., Richmond 19, Secretary.

Washington State Medical Association, Seattle, Olympic Hotel, Sept. 28-Oct. 1. Dr. Harold E. Nichols, 327 Cobb Building, Seattle, Secretary.

Wisconsin, State Medical Society of, Milwaukee, Hotel Schroeder, Oct. 6-8. Mr. Charles H. Crownhart, 110 E. Main St., Madison 3, Secretary.

GOVERNMENT SERVICES

ARMY.

MEAT FOR THE ARMED FORCES

The War Department announced September 12 that only 2.2 per cent of the nation's total meat production was procured for the armed forces by the Quartermaster Corps during the first six months of this year. The total meat production for the United States for this period was 11,522 million pounds, of which the Quartermaster Corps procured 254,016,032 pounds. The Quartermaster Corps purchases meat for the Army, Navy, Maritime Commission, Coast Guard and Veterans Administration; procurement includes also requirements for civilian employees of the armed forces in the occupied zones overseas. During this period the Quartermaster Corps procured also 12,891,444 pounds of poultry and 8,152,778 pounds of fish.

PUBLIC HEALTH IN KOREA

The War Department reports that the Korean Medical Society was organized May 10 and that plans were made for organizing sections within the association. More than one hundred scientific papers were submitted at the organization session.

The second phase of the cholera control program was about 90 per cent completed by the end of May. This phase concentrated on the immunization of all persons within the coastal area. The third phase, to cover large inland cities, was initiated May 15. Cholera vaccine dispensed in the four weeks ending May 23 was about double the amount dispensed during the previous four week period.

NURSES MAY APPLY FOR COMMISSION UNTIL SEPTEMBER 30

The Surgeon General, Major Gen. Raymond W. Bliss, announces that applications for regular army commissions in the Army Nurses Corps and Women's Medical Specialist Corps may be submitted up to September 30. Applicants who are unmarried with no dependents under 14 years of age and who have had previous military service are eligible for commissions. The age limit for nurses is 21 to 35 years and for the Women's Medical Specialists Corps from 21 to 45 years. After September 30 the age limit in both Corps will be 21 to 28 years. Pay and benefits for these commissioned officers will be the same as that of all other Army officers. Forms for applying for commissions can be obtained from Army hospitals, district nursing associations, the Surgeon General's Office, War Department, Washington, D. C., and from other Army headquarters.

ARMY AWARDS AND COMMENDATIONS

Colonel Arden Freer

The Legion of Merit has been awarded to Colonel Arden Freer, M. C., U. S. A. (Retired). The citation read as follows: He performed exceptionally meritorious service from December 1941 to October 1942, as Chief of Medical Service, Walter Reed General Hospital; as Director of the Department of Internal Medicine, Army Medical Center, and later as Executive Officer, Walter Reed General Hospital. He ably headed the professional staff while it was responsible for ultimate decision in many complicated professional and administrative problems. He played an important role in the formulation and implementation of teaching measures and text material and in supervision of important training courses incident to the orientation and indoctrination of medical officers who were to serve in responsible professional and administrative positions throughout the world. Colonel Freer who later served in the Surgeon General's Office has also been awarded the Distinguished Service Medal and the Army Commendation Ribbon. Dr. Freer graduated from New York University College of Medicine, New York, in 1913 and entered military service May 18, 1916. He retired from the Army Jan. 1, 1947 and is now executive officer, Office of Assistant Medical Director for Professional Services, Veterans Administration, Washington, D. C.

NAVY

NAVY ADOPTS NEW NOMENCLATURE

To promote the use of standardized titles for diagnoses, the Bureau of Medicine and Surgery of the Navy has adopted the "Standard Nomenclature of Disease," sponsored by the American Medical Association, as the criterion for diagnostic nomenclature terms. The Navy nomenclature is now in process of revision to bring the diagnostic titles into agreement with the standard nomenclature. It is contemplated that the International Statistical Classification of Diseases, Injuries and Causes of Death, which is now being revised by the World Health Organization, will be adopted by the Navy to serve its statistical purposes. These two changes will increase the value of naval medical statistics.

MEDICAL INSPECTION TRIP

Rear Admiral Dan Hunt (MC), general inspector for the Bureau of Medicine and Surgery, left September 9 for the Pacific Coast to inspect the medical facilities in the Eleventh, Twelfth and Thirteenth Naval Districts. En route, Admiral Hunt inspected the hospital at the Naval Training Station, Great Lakes, Ill., and other medical facilities in the Eighth and Ninth Naval Districts.

NAVY AWARDS AND COMMENDATIONS

Commander Eugene P. Harris

The Secretary of the Navy recently awarded the Commendation Ribbon to Commander Eugene P. Harris (MC). The citation reads as follows: "For outstanding service as Safety Officer, Joint Task Force ONE, during operation Crossroads, from Aug. 15 to Oct. 10, 1946. Commander Harris assumed his responsibilities in charge of safety operations, including radiologic safety, during a critical phase of the operation. Working tirelessly and with resourceful initiative, he reorganized the radiologic safety operations, systemized safety technics and accumulated valuable technical information despite the lack of trained personnel and inadequate technical facilities. In addition, he was largely responsible for the safe removal of ammunition from ships radiologically hazardous. By his professional skill and judgment and his determined effort in the face of great difficulty, Commander Harris contributed materially to the success of operation Crossroads. His conduct throughout upheld the highest traditions of the U. S. Naval Service." Dr. Harris graduated from the University of Texas Medical School in 1935 and entered the naval service in June 1937.

VETERANS ADMINISTRATION

A TRIBUTE TO THE MEDICAL PROFESSION

Following an extensive tour of Veterans Administration hospitals, Dr. Paul R. Hawley, Chief Medical Director, outlined his reactions to what he saw of the medical program. Among other things he stated that in the last fiscal year a total of 386,614 veterans were admitted to VA hospitals compared to 271,299 for the previous fiscal year. The Veterans Administration hospital plant had 101,273 available beds compared to 87,369 at the end of the previous fiscal year. A total of 2,744,602 persons were given medical examinations compared with 1,036,634 in the previous year. This number did not include the dental examinations, which numbered 564,171 and 85,537, respectively.

Dr. Hawley attributed the progress made to two principal factors—enough money to do the job and a staff of sufficient size and quality to do it well. With reference to the difficult situation of the recent past Dr. Hawley said: "Until a short time ago, our relatively inadequate medical budget and the insufficient number of personnel made it physically impossible for even our best trained and most competent doctors to provide the kind of medical care they were capable of giving and eager to give to the veteran patient. Professional stimulation through close association with the finest medical schools, the challenge of research, and opportunities for professional growth and advancement were only dreams in those difficult days. But despite the overcrowded hospitals, staggering patient loads and inadequate equipment and personnel, many of our doctors struggled to the limit of their endurance to provide the best medical care possible under the circumstances. That they were able to accomplish as much as they did is a tribute to their sense of obligation to their calling and their concern for their patients' welfare.

"In contrast to the conditions I have described, funds are now available to assure us not only that medical services will not be seriously curtailed, but—more important—that the quality of medical care will not be jeopardized. But this assurance is ours only if these funds are widely used so that every dollar spent contributes directly to the attainment of our major goals.

"While the progress we have made would have been quite impossible without the necessary funds, it would have been equally impossible without the necessary personnel. Thanks to the interest of the medical profession as a whole in the VA medical program, we have been able to secure the services, on a full-time, part-time or consultant basis, of the country's most gifted professional men. Our entire staff—both those who have seen long service with the VA and those who joined us more recently—has responded magnificently to the professional stimulation and guidance these leaders have provided.

"In any medical program, it is the individual doctor, dentist, nurse and attendant who is finally responsible for the quality of medical care. Without their unstinting support and personal competence, the most ambitious and well planned medical program is inevitably doomed to failure. Inspired by unparalleled opportunities for practicing the finest medicine, both our older and our newer men, sharing their knowledge, skill and enthusiasm, have contributed equally to the creation of a well balanced medical staff which is bringing to the veteran's bedside the very best in medical theory and practice."

RELEASE FROM HOSPITAL PAPER WORK

The chief medical director of the Veterans Administration, Dr. Paul R. Hawley, has directed that registrars' offices be set up in Veterans Administration hospitals to handle the routine paper work that nonprofessional personnel can process, in order to relieve physicians, nurses and technicians so they may have more time for the care of veteran patients. The registrar's office will handle the paper work in connection with admission, transfer and dismissal of patients; maintain clinical forms and reports; develop statistical data; direct administrative ward procedures; supervise all ward clinical and stenographic personnel, and take care of patients' clothing and valuables.

PERSONAL

Dr. William F. English has resigned from the staff of the Veterans Administration Hospital in Grand Rapids and will return to private practice in Saginaw, Mich.; he will be succeeded on the hospital staff by Dr. William H. Davis Jr., a native of North Carolina, a graduate of Indiana University School of Medicine and a veteran of World War II.

Dr. Clement C. Troensegaard, formerly of Pasadena, has been appointed chief of physical medicine at the Birmingham Veterans Administration Hospital, Van Nuys, Calif., where he has been on duty as chief of the patients receiving division since April. Dr. Troensegaard served in the Pacific in the Navy during the recent war.

PUBLIC HEALTH SERVICE

CONFERENCE ON NOMENCLATURE OF THE Rh FACTORS

The Surgeon General, U. S. Public Health Service, has appointed an advisory board to designate the proper names for the several anti-Rh blood typing serums licensed under the Biologics Law. The desire is to have recommended a system of nomenclature which will be adequate to cover this phase of human genetics and one which can be readily adapted to clinical use, medical teaching and laboratory diagnosis.

The members of the board are Drs. William B. Castle Jr., professor of medicine, Harvard Medical School; Maxwell M. Wintrobe, professor of medicine, University of Utah School of Medicine, and Laurence H. Snyder, professor of medical genetics, University of Oklahoma School of Medicine.

The conference will convene at 9:30 a. m. October 20 in the Hotel Statler, Washington, D. C., and will continue on October 21.

The board will be pleased to hear evidence from persons qualified in this field. Those having evidence to present should communicate in advance with Dr. M. V. Veldee, Chief, Biologics Control Laboratory, National Institute of Health, Bethesda 14, Md. Others desiring to attend will be welcome, but advance notice of interest will be appreciated so that meeting accommodations may be assured. Copies of the speakers' remarks, if extensive, are desired by the board.

NATIONAL ADVISORY SEROLOGY COUNCIL

The name of the Committee on the Evaluation of Serodiagnostic Tests for Syphilis has been changed to the National Advisory Serology Council, and its scope has been enlarged. These recommendations were made by the committee last May and have been approved by the Surgeon General of the U. S. Public Health Service. At the last meeting of the committee the chairman, Dr. J. F. Mahoney, Director of the U. S. Public Health Service Venereal Disease Research Laboratory on Staten Island, N. Y., discussed the new cardiolipin-lecithin antigen which, because of the greater specificity of tests results, appears to be replacing the older antigens.

PERSONAL

Dr. Joseph S. Spoto has been assigned as assistant chief of the Venereal Division, U. S. Public Health Service, Washington, D. C. Dr. Spoto, formerly of Tampa, Fla., joined the Public Health Service in 1941. He was transferred to Mexico City in 1944 to assist the Mexican government in organizing a venereal disease training center; more recently he was chief of the venereal disease control activities in the Caribbean area with headquarters in Guatemala City. He is a graduate of the Tulane University School of Medicine, New Orleans.

CORRECTION

Tomlinson, William A.—The Surgeon General's Office reports that the name of William A. Tomlinson, Springfield, Ill., was erroneously included in the list of officers recommended for relief from active duty in The Journal, July 26, 1947, p. 1104. This officer is still on active duty.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

ARKANSAS

Fifth District Medical Society Meeting.—This society will meet October 30 in Camden. At the dinner following the reception short talks will be made by officers of the Arkansas Medical Society: Drs. Lorenzo T. Evans, president; William R. Brooksher, secretary, and Euclid M. Smith, chairman of the council. Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL, will speak at the public relations meeting at the Camden Municipal Auditorium, 7:30 p. m. Gov. Ben Laney will also appear on the program along with Sen. James W. Fulbright, Fayetteville, and Congressman Oren Harris, Belton. All members of the Arkansas Medical Society are invited to attend and are requested to make reservations for the dinner with Dr. Rufus B. Robins, Camden.

CALIFORNIA

Gift to Library.—The library of the College of Medical Evangelists, Loma Linda-Los Angeles, has received the gift of many textbooks and bound files of medical journals from the library of Dr. Lloyd E. Smith, an alumnus. Dr. Smith, who practiced in San Bernardino and was a frequent visitor at the college, died May 1.

Memorial Lecture in London.—Dr. John H. Lawrence, assistant professor of medical physics, University of California Medical School, Berkeley-San Francisco, delivered the Mackenzie-Davidson Memorial lecture of the Institute of London on July 17 at the invitation of the British Institute of Radiology. He received the institute's annual award.

Medical Apprenticeships.—Three medical students of the University of California Medical School, Berkeley-San Francisco, have completed summer apprenticeships under the guidance of practicing California physicians, in accordance with a plan initiated by Dr. William J. Kerr, professor of medicine. Dr. Kerr said that the purpose of the plan is to give medical students an opportunity to learn first hand the practical operation of private medical practice. The three students had completed the third year in the medical school.

CONNECTICUT

Chairman of Tuberculosis Commission.—Dr. Joseph I. Linde, health officer for the City of New Haven and clinical professor of pediatrics and public health, Yale University School of Medicine, New Haven, was recently appointed chairman of the Connecticut State Tuberculosis Commission, of which he has been a member since 1939. Dr. Linde is also a member of the Building Program Committee for the State's Humane and Welfare Institutions, created at the last session of the general assembly.

Dr. Chaffee Honored.—The trustees of the Sharon Hospital, Sharon, voted unanimously to name the original building of the hospital "The Chaffee Pavilion" and to place a plaque at the main entrance expressing appreciation of Dr. Jerome S. Chaffee's long and untiring service in managing the hospital. The board believes that this action not only expresses the sentiment of the trustees but also of members of the communities which have benefited from the service which this hospital has rendered during the past thirty-eight years.

DISTRICT OF COLUMBIA

Chest Physicians Meet.—The fourth biannual meeting of the Potomac Chapter of the American College of Chest Physicians will be held in the District of Columbia Medical Society Building, October 5, at 1 p. m. On the scientific program speakers will be Dr. Herbert C. Maier, New York, "Recent Trends in the Surgical Therapy of Pulmonary Tuberculosis"; Dr. Osler A. Abbott, Atlanta, Ga., "Etiology of Hemoptysis Associated with a Negative Plain Chest X-Ray"; Dr. Arthur M. Olsen, Rochester, Minn., "Role of Inhalation Therapy in Management of Bronchiectasis"; Dr. David Salkin, Hopemont, W. Va., "Postmortem Pneumothorax," and Dr. Peter A. Herbut, Philadelphia, "The Cytology of Bronchial Secretions in Carcinoma of the Lung." A short business meeting at 5:15 p. m. and a dinner at the Mayflower Hotel at 6:30 p. m. will follow. At 8 o'clock an X-Ray Conference will be held.

The Eighteenth Annual Meeting.—The eighteenth annual meeting of the Medical Society of the District of Columbia will be held at the Hotel Statler October 6-8 under the presidency of Dr. William P. Herbst Jr. Guest speakers on the program include:

Herbert W. Schmidt, Rochester, Minn., Recognition and Management of Esophageal Disease.
John H. Garlock, New York, Present Trends in Gastric Surgery.
Henry L. Bockus, Philadelphia, Role of the Pancreas in Gastrointestinal Disorders.
Geza de Takats, Chicago, Surgery of Hypertension.
John T. King, Baltimore, Pseudoangina.
Walter Kempner, Durham, N. C., Medical Management of Hypertension—Rice Diet.
Richard W. Te Linde, Baltimore, Diagnosis and Treatment of Carcinoma of the Uterus.
John Caffey, New York, Status Lymphaticus.
Douglas N. Buchanan, Chicago, Subdural Hematomas of Newborn.
Elvin M. Jellinek, Sc.D., New Haven, Conn., Newer Approaches in the Care of the Alcoholic.

On Monday afternoon at 3:15 there will be a panel discussion on "Upper Extremity Pain" with William E. Nachlas, Baltimore; M. Barnes Woodhall, Durham, N. C., and Gerald H. Pratt, New York, participating. Tuesday afternoon a panel discussion on "Hyperfunctioning Endocrine Tumors" will include Joseph C. Aub, Boston, and Meyer M. Melicow, New York. Wednesday afternoon's panel will be on "Antibiotics—Experimental Trends." Monday's luncheon speaker will be Louis A. M. Krause, Baltimore, "Trends in Medicine"; Wednesday's speaker, George F. Lull, Secretary and General Manager, American Medical Association, Chicago, "Activities of the Headquarters of the American Medical Association." At the annual dinner Wednesday at 7:30 p. m. Edward L. Bortz, Philadelphia, President of the American Medical Association, will speak on "Medical Statesmanship." A public meeting will be held Tuesday evening at 8:15 at which Dr. George E. Gardner, Boston, will speak. There will be exhibits, demonstrations and motion pictures. Medical officers in the Army, Navy and Public Health Service and physicians employed by the Veterans Administration are invited to be guests of the society and will not be required to pay a registration fee.

ILLINOIS

Two Down State Postgraduate Conferences.—The first of a series of twelve postgraduate conferences, sponsored by the Postgraduate Education Committee of the Illinois State Medical Society and authorized by the Council, has been arranged for the Ninth Councilor District, October 2, at the Elks Hall, Marion, beginning at noon and extending through the evening. The district includes the counties of Edwards, Franklin, Gallatin, Hamilton, Hardin, Jefferson, Johnson, Massac, Pope, Saline, Wabash, Wayne and Williamson. The second conference will be held for the Sixth Councilor District at the Dunlap Hotel in Jacksonville, October 9 from 12:30 p. m. extending through the evening. The district includes the counties of Adams, Brown, Cass, Pike, Scott, Calhoun, Greene, Jersey, Madison, Macoupin and Morgan. The lecturers for both conferences are mostly from Chicago.

Chicago

The Belfield Lecture.—At the meeting of the Chicago Urological Society, October 16, at the Palmer House, the nineteenth annual William T. Belfield Memorial Lecture will be given by Dr. Hans Selye, McGill University, Montreal. He will be the first foreign speaker in the Belfield lecture series.

Ex-Cook County Hospital Interns' Reunion.—Reunion for all alumni interns of Cook County Hospital will be held November 7 at Cook County Hospital in celebration of the hundredth anniversary in founding of a charity hospital for Cook County in 1847. Dedication of the Tice Memorial Library will be held at 4:30 p. m. and a reunion banquet at the Congress Hotel at 6:30. For information address William J. Baker, M.D., secretary-treasurer, Cook County Hospital Internes' Alumni Association, 7 West Madison Street, Chicago 2.

Chemists Honor Dr. Volwiler.—The Honor Scroll of the American Institute of Chemists will be presented to Ernest H. Volwiler, Ph.D., executive vice president, Abbott Laboratories, October 10 at a dinner of the Chicago chapter in the Furniture Club at 7 p. m. The scroll is being given for Dr. Volwiler's contributions to the field of medicinal chemistry, for his work in the organization of research programs and his active part in furthering the work of scientific societies. Dr. Robert E.

Wilson, Mount Vernon, Ind., and Albert E. Sidwell Jr., Ph.D., director of chemical laboratories of the American Medical Association, will speak at the dinner. Reservations may be made with Mary Alexander, Universal Oil Products Company, 310 South Michigan Avenue.

Graduate Course in Gastroenterology.—The Chicago Medical Society has announced its second postgraduate course October 27-November 1, focusing attention on gastroenterology. It is designed for both the specialist and the general practitioner. All sessions will be held at Thorne Hall. Registration will be limited to one hundred. The out of state faculty includes:

Russell S. Boles, Philadelphia, Modern Conception of Cirrhosis of Liver.
Fr[illegible], Minn., Circulation of the Liver and Its [illegible].
As[illegible], [illegible] York, Vagotomy.
Sara M. Jordan, Boston, Functional Digestive Diseases.
George B Eusterman, Rochester, Minn., Late Sequelae of Gastric Surgery, Problems in Diagnosis and Treatment.
Richard B. Cattell, Boston, Management of Carcinoma of the Bowel.
John H. Fitzgibbon, Portland, Ore., Diagnosis of Lesions Near the Cardia.
Walter C. Alvarez, Rochester, Minn., What Is the Matter with Patients Always Tired?
Frank H. Lahey, Boston, Surgical Treatment of Peptic Ulcer.

This course, like the one in cardiovascular diseases October 20-25, has been approved for veterans' training. For details of veteran registration see THE JOURNAL, September 20, page 169. The fee is $50.

INDIANA

The Ninety-Eighth Annual State Meeting.—The ninety-eighth annual session of the Indiana State Medical Association will be held at French Lick, October 28-30, under the presidency of Dr. Floyd T. Romberger, LaFayette. The scientific program will open Wednesday morning with the president's address. On the afternoon program Dr. Henry N. Harkins, Seattle, among others, will participate in a symposium on "The Treatment of Burns." Section meetings on medicine, surgery, ophthalmology and otolaryngology, anesthesia and general practice are scheduled for the afternoon. Guest speakers on the general scientific sessions resuming Thursday morning include:

William S. Middleton, Madison, Advances in Therapy of Coronary Disease.
Alexander R. MacLean, Rochester, Minn., The Paradox: Psychoneurotic Malingering.
George T. Pack, New York, Cancer of the Breast; Its Early Diagnosis and Treatment.
Philip Lewin, Chicago, Treatment of Poliomyelitis in the Early Stages.
Lee Foshay, Cincinnati, Use of Streptomycin in the Treatment of Tularemia.
Bruce K. Wiseman, Columbus, Ohio, Modern Treatment of the Anemias.

At the annual banquet Thursday evening Dr. Roscoe L. Sensenich, South Bend, President-Elect of the American Medical Association, will speak. Other meetings during the session will be the Indiana Health Officers' Conference, state and county Conservation of Vision committees, state and county Anti-Tuberculosis committees, the Indiana chapter of the American College of Chest Physicians and the Indiana Roentgen Society. The Woman's Auxiliary will meet October 28-30 at the hotel.

MASSACHUSETTS

Dr. Howe Joins Smithwick Foundation.—Dr. Chester W. Howe, Framingham, has resigned from the active staff of the Framingham Union Hospital to accept an appointment at the Smithwick Foundation, where he will conduct research on wound infections. He will have available the facilities of the Massachusetts Memorial hospitals, as well as those of the Smithwick Foundation and Boston University School of Medicine, all of Boston, through which funds will be made available. Before going to Framingham Dr. Howe was an instructor in surgery at Boston University School of Medicine. He had also held appointments at the Rhode Island, Providence Lying-In and Pondville hospitals.

Dr. Lindemann Heads Department of Social Relations.—Dr. Erich Lindemann, associate professor of psychiatry, Harvard Medical School, Boston, has joined the Harvard University Faculty of Arts and Sciences to broaden the scope of the new department of social relations established last year. The department was formed to break down the limitations of individual departments in working on common problems of social relations. Dr. Lindemann is a graduate of Cologne University, Germany, 1924, and came to Harvard Medical School in 1935 as a Rockefeller fellow in neurology and psychiatry. He was an instructor in psychiatry from 1937 to 1941, when he was made an associate in psychiatry as well as an instructor in psychiatric industrial hygiene at the Harvard School of Public Health.

MICHIGAN

Counties May Vote for Health Departments.—Under new legislation the twelve counties in the state which do not have the services of a local health department may now take the initiative in providing them. A petition signed by 5 per cent of the electors of the county can require the board of supervisors to place the question of establishing a health unit on the ballot at the next general election. A majority vote can require the establishment of the department.

Hearing Consultants Available to Michigan Schools.—The Michigan Department of Health is again offering the services of two hearing consultants to Michigan schools in continuation of the hearing program begun in January 1943. More than thirty-eight counties have already requested the services of consultants. Each child with a hearing loss detected by tests using an audiometer is taken to a hearing specialist for examination and medical care. Since the program began, group hearing tests have been given to 214,290 children in forty-three counties in the state. Of these, 3 per cent showed some loss of hearing. Of those who received medical treatment, 75 per cent improved, about 50 per cent to normal hearing. Requests for the hearing conservation program are made through local health departments.

MISSISSIPPI

Medical Education Awards to Encourage Rural Practice.—The Mississippi Medical Education Board has approved ninety-three medical aid awards to students who have agreed to return to rural Mississippi to practice medicine after the completion of their education. The students may study in any university of their choice. The board was created in accordance with legislation passed by the legislature in 1946.

Changes in Health Officers.—Dr. James A. Sproles Jr., Columbia, assumed duties as director of the Adams County health department July 1, succeeding Dr. Kenneth W. Navin, who became district supervisor for the state board of health. Dr. Sproles, a 1936 graduate of Tulane University of Louisiana School of Medicine, New Orleans, joined the state department of public health in 1939 and prior to entering the army in 1944 was health officer for Marion County. He has been health director for Alcorn and Tishomingo counties.

MISSOURI

Mediterranean Theater Surgeons' Meeting.—The Excelsior Surgical Club, a national organization of surgeons who served in the Mediterranean theater during World War II, will meet in St. Louis, October 17-18. The Edward D. Churchill lecture will be presented by Dr. Evarts A. Graham, St. Louis, at the St. Louis Medical Society, 8:30 p. m., October 17. The lecture was established in 1946 in honor of Dr. Churchill, the John Homans professor of surgery at Harvard Medical School, Boston, who was chief surgical consultant in the Mediterranean theater of operations during World War II.

Jackson County Health Forum.—The Jackson County Health Forum 1947-1948 lecture series began September 17 with Dr. M. Murray Peshkin, New York, speaking on "Hay Fever and Asthma." Other scheduled lectures, all open to the public without charge, are: Dr. Arnold S. Jackson, Madison, Wis., "Goiter and Other Diseases of the Thyroid Gland"; Dr. Austin E. Smith, Chicago, "Pink Pills and Pale People"; Dr. Franklin G. Ebaugh, Denver, "The Mind and the Body"; Dr. Arlie R. Barnes, Rochester, Minn., "Heart Disease"; Dr. Herman M. Jahr, Omaha, "Why I Can't Sleep," and Dr. Morris Fishbein, Chicago, Editor, THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, "Keep Fit and Like It." All lectures will be held in the Little Theatre of the Municipal Auditorium at 8:15 p. m. on the third Wednesday of each month.

NEW YORK

Infant Diarrhea Closes Hospital Ward.—The maternity ward at Deaconess Hospital, Buffalo, was closed August 27, pending results of an investigation by the health department into an outbreak of diarrhea blamed for 8 infant deaths in the preceding two weeks. A total of 36 cases of the illness was reported.

Society Elections.—The officers of the New York Psychoanalytic Society for 1947-1948 are Dr. Sandor Lorand, New York, president; Dr. William H. Dunn, New York, vice president; Dr. John Frosch, New York, secretary, and Dr. Harry I. Weinstock, New York, treasurer.——At the annual conference of health officers and public health nurses, Saratoga Springs, July 28-31, the New York State Health Officers Association elected Dr. George E. Sanders, Greece, president; Dr. H. Burton Doust, Syracuse, treasurer, and Dr. Eldred J. Stevens, Hammondsport, secretary.——The New York State Association of School Physicians at its annual session on June 28 elected Dr. Adele Brown, Oswego, president, and Dr. Adfur E. Maines, Kenmore, secretary-treasurer.

Rochester Academy Receives Library Gifts.—A library estimated at 1,500 volumes has been willed to the Rochester Academy of Medicine by the late Dr. Clarence V. Costello, Holland, Mich., and will be set up in a special collection available in the fall. Dr. Costello was formerly an instructor in surgery at the University of Rochester School of Medicine and Dentistry. He died May 31.——"The Edward L. Hanes Collection," including more than one hundred and forty volumes on neurology and allied subjects, two hundred books on general medicine, bound journals and reprints, has been given to the Rochester Academy of Medicine. The collection was that of the late Dr. Edward L. Hanes, a leader in academy affairs for many years, and has been presented by his widow to the academy.

New York City

Permit Required of Delicatessen Stores.—A permit from the health department will be required of all delicatessen stores, box-lunch and catering firms beginning November 1, in accordance with an amendment to the sanitary code adopted by the board of health September 9. The amendment was passed after a survey that had revealed unsanitary conditions in such places.

Hofheimer Foundation Laboratories.—A $75,000 grant from the Nathan Hofheimer Foundation, Inc., New York, has been received by the New York University-Bellevue Medical Center Fund with a stipulation that it be used to establish the Nathan Hofheimer Foundation Laboratories for basic research in psychosomatic disorders. The sum has been added to the New York University-Bellevue Medical Center Fund, whose goal is $15,575,000.

Hospital News.—Hospital construction costing $7,698,163 has been authorized by the board of estimate of New York City. The largest item was $4,863,000 for the new Florence Nightingale Hospital at 163d Street and Fort Washington Avenue. The board also appropriated $1,365,000 for foundation work on a new chronic disease hospital on Welfare Island. Other appropriations were: $262,000 for modernization of equipment in all hospitals and $881,500 for preliminary work on the projected new tuberculosis and chronic disease hospital on the grounds of Kings County Hospital. Immediate construction of the first part of the $7,000,000 Alfred E. Smith Memorial Wing of St. Vincent's Hospital has been authorized as a part of the $25,000,000 building construction program of the New York Archdiocese.

OKLAHOMA

Annual Meeting of Clinical Society.—The seventeenth annual meeting of the Oklahoma City Clinical Society will be held October 27-30 at the Biltmore Hotel, Oklahoma City. The program comprises a clinical pathologic conference, general assemblies, postgraduate courses, round table luncheons, dinner meetings and commercial exhibits. Among the guests will be Drs. Edward D. Allen, Chicago; William A. Altemeier, Cincinnati; Carl E. Badgley, Ann Arbor, Mich.; Edward L. Bortz, President of the American Medical Association, Philadelphia; A. Carlton Ernstene, Cleveland; Wiley D. Forbus, Durham, N. C.; Thomas E. Jones, Cleveland; H. Dabney Kerr, Iowa City; Linwood D. Keyser, Roanoke, Va.; Edward L. King, New Orleans; Frank D. Lathrop, Boston; George M. Lewis, New York; Samuel F. Marshall, Boston; Herbert C. Miller Jr., Kansas City, Kan.; Edith L. Potter, Chicago; C. Wilbur Rucker, Rochester, Minn.; Cyrus C. Sturgis, Ann Arbor, Mich., and Elmer G. Wakefield, Rochester, Minn. They will discuss gynecology, surgery, medicine, pathology, roentgen therapy, urology, otolaryngology, ophthalmology, dermatology and pediatrics. The registration fee is $15. For further information address the Executive Secretary, 512 Medical Arts Building, Oklahoma City.

SOUTH CAROLINA

Dr. Guyton Heads State Hospital Division.—The state board of health has appointed Dr. Clarence L. Guyton, Greenville, as head of the newly established hospital division of the state board of health. The division will have a full time staff consisting of a director, an architect, an engineer and clerical and stenographic help. The department will carry out provisions according to the State Hospital Construction Act, which requires the licensing, inspection and regulation of hospitals and related institutions as defined in the act; creates a hospital licensing council, and prescribes its composition and power. Dr. Guyton was recently health commissioner of Greenville. Before coming to the state board of health in 1936, Dr. Guyton was in administrative charge of a hospital in North Carolina.

WASHINGTON

University Accepts Ophthalmology Library.—Dr. Frederick W. Adams, Carmel, Calif., a retired physician of Seattle, has presented the new medical school of the University of Washington, Seattle, a collection of books on ophthalmology. There are two hundred and fifteen bound volumes and many unbound medical journals. Since retirement Dr. Adams has indulged in his hobby and has been a frequent exhibitor in the Physicians Art Association.

Community Honors Physician.—Dr. Carl J. Hoffmann, Woodland, was guest of honor at a picnic given in his honor at Ariel Dam on August 24 and attended by over 3,000 patients and friends. A leather book with his likeness engraved thereon containing photographs and clippings was presented along with a check for $2,600. The latter the doctor said would be used for some worthy community project. Dr. Hoffmann has been practicing in Woodland for over thirty-eight years.

Tumor Registry Set Up.—The Washington State Tumor Registry has been set up at the University of Washington, Seattle, under the sponsorship of the state society of pathologists, the University of Washington School of Medicine and the state health department. This clearing house will afford physicians throughout the state consultation service in diagnosing cancer. Pathologists throughout Washington will submit to the registry duplicate microscopic slides of all cancerous and questionable tumors as well as certain benign tumors coming into their laboratories. The expenses of the registry will be defrayed by the cancer control section of the state health department, and the pathologists' society will act in an advisory capacity. Practicing pathologists under the registry work free of charge should indigent patients need medical aid.

WEST VIRGINIA

Annual District Health Conferences.—The annual northern district health conference will be held under the auspices of the state department of health at the Stonewall Jackson Hotel, Clarksburg, October 17. Among the speakers will be Dr. Newman H. Dyer, Charleston, state health commissioner, who will speak on the tuberculosis law passed by the 1947 legislature, and Dr. Alexander Witkow, director, Bureau of County Health Work, whose topic will be "The Next Year in County Health Work." Section meetings will be held for health officers, public health nurses and sanitarians. The southern district health conference is scheduled for Beckley, October 20. Subjects to be discussed include the value of sanitation in recreation facilities, improved school sanitation, keeping active tuberculosis patients in sanatoriums, and community-school health councils. Section meetings will be held in the afternoon.

Foundation Appoints State Medical Advisory Committee.—A West Virginia Medical Advisory Committee to the National Foundation for Infantile Paralysis has been appointed by Dr. Hart E. Van Riper, medical director of the foundation. The committee is composed of Drs. Frank J. Holroyd, Princeton; Cecil O. Post, Clarksburg; Justus C. Pickett, Morgantown; L. Rush Lambert, Fairmont; Jack Basman and Howard A. Swart, Charleston, and Mr. Charles Lively, Charleston, executive secretary of the West Virginia State Medical Association, ex officio. The committee has been appointed to promote cooperation between the National Foundation and the medical profession in West Virginia, with the idea of providing the state representative competent medical advice in matters pertaining to poliomyelitis epidemic preparedness, epidemic medical service and health education.

WISCONSIN

Graduate Course in Internal Medicine.—The American College of Physicians is sponsoring a course in internal medicine at the University of Wisconsin Medical School, Madison, November 3-14. Registration for participation will be done through the American College of Physicians, 4200 Pine Street, Philadelphia 4. The fee to college members will be $60 and to nonmembers $120. Maximum registration will be twenty-five.

Course in Cardiology.—The University of Wisconsin Medical School will repeat its intensive course in cardiology October 20-24. The work includes rudiments of electrocardiographic interpretation, a review of the principles of orthodiascopy, the therapy of hypertensive cardiac disease and the arrhythmias, a review of the current concepts of the treatment of rheumatic fever and other material of a practical character. The course, limited to fifteen physicians, fee $25, will be under the supervision of Drs. Chester M. Kurtz and Herman H. Shapiro of the department of cardiology. Details may be obtained from Dr. Llewellyn R. Cole, Coordinator of Graduate Medical Education, The Medical School, Madison 6, Wis.

GENERAL

Southern Psychiatric Association.—The annual meeting of the Southern Psychiatric Association will be held at the Hotel Thomas Jefferson, Birmingham, Ala., October 13-14, under the presidency of Dr. Robert H. Felix, Washington. Numerous prominent speakers will appear on the program. All members of the Medical Association of Alabama are cordially invited to attend.

American Public Health Association Meeting.—The seventy-fifth annual meeting of the American Public Health Association in Convention Hall, Atlantic City, N. J., October 6-10, will be under the presidency of Dr. Harry S. Mustard, New York. There will be section meetings on food and nutrition, epidemiology, maternal and child health, school health, engineering and industrial health, public health education, nursing, industrial hygiene and dental health.

Van Meter Prize Award.—The American Association for the Study of Goiter again offers the Van Meter Prize Award of three hundred dollars for the best essays submitted concerning original work on problems related to the thyroid gland. Essays may cover either clinical or research investigations, should not exceed 3,000 words and must be in English, typewritten in double spaced copy. The award will be made at the annual meeting of the association in Toronto May 6-8, providing essays of sufficient merit are presented in competition. Address Dr. Thomas C. Davison, Corresponding Secretary, 207 Doctors Building, Atlanta 3, Ga.

Study of Congenital Malformations and Maternal Infection.—To collect data on any relationship between maternal infections and congenital malformations, the American Academy of Pediatrics and the National Society for the Prevention of Blindness are sponsoring a nationwide survey. Questionnaires are being sent to obstetricians, ophthalmologists and pediatricians, seeking the reporting of cases of German measles in expectant mothers and of children with congenital defects that might be attributed to other infections in the expectant mother, such as measles, chickenpox, mumps and influenza. One year will be spent in collecting data; then a report will be made. Data will be studied by the following committee: Drs. Herbert C. Miller, professor of pediatrics, University of Kansas School of Medicine, Lawrence-Kansas City, Kan.; Stewart H. Clifford, Weston, Mass.; James L. Wilson, Ann Arbor, Mich., and Herman Yannet, Southbury, Conn. Physicians knowing of cases are urged to register them with Dr. Miller, chairman of the committee.

Opportunity for Careers in Academic Medicine.—An opportunity to start a career in academic medicine is offered by the John and Mary R. Markle Foundation to young scientists with the necessary training to hold regular faculty appointment and to conduct original research. The new program of postfellowship grants will be conducted in cooperation with accredited medical schools in the United States and Canada. Grants of $25,000, payable to the cooperating school at the rate of $5,000 annually toward the support of each successful candidate or his research or both, will be available beginning with the academic year 1948-1949. If the plan proves successful the foundation will appropriate a total of $1,250,000 payable to the schools by 1953. Candidates will be recommended by medical schools and will be limited to young men and women with a particularly strong interest in research and teaching in any of the clinical or preclinical sciences or in the sciences basic to medicine. They will have had training in some special field or combination of fields to qualify them to receive a regular faculty appointment and to conduct original research. The final choice of "Scholars in Medical Science" will be made, on the basis of the schools' recommendations, by regional committees appointed by the foundation. About fifty will receive appointments during the five year period. The school will determine salary and academic rank, encourage research by setting reasonable limits on nonresearch activities, provide laboratory facilities and, if necessary, make a financial contribution toward support of the scholar's work. The program is the result of a survey of medical research and education recently made by the foundation, which shows that while there are scholarships and other forms of financial aid for the student in the course of his scientific training, and while there are funds available to the scientist once his name is made, there are few sources of help at the beginning of the career of the man who chooses academic medicine. Persons interested in being considered as candidates are referred to deans of accredited medical schools for further information.

Prevalence of Poliomyelitis.—Reports of cases of poliomyelitis for the periods indicated have been received from the division of public health methods, U. S. Public Health Service:

Deaths in Foreign Countries

Professor Ferdinand Flury, M.D., for many years professor of pharmacology, University of Würzburg, Bavaria, died recently, aged 70. He was very active as a research worker in the field of toxicology. With Zangger he edited "Lehrbuch der Toxikologie," Berlin, 1928, and in collaboration with F. Zernik he wrote "Schädliche Gase," Berlin, 1931.

Marriages

Marshall Arthur Freedman, Gunter Field, Ala., to Mrs. Betty Borwick Shapiro at Denver, August 16.

Charles J. Baker, to Mrs. Virginia Gilliland, both of Fort Dodge, Iowa, in Webster City, March 29.

Louis Franklin Burkley III to Miss Martha-Anne Dougherty, both of Easton, Pa., May 23.

W. David Francisco, Kansas City, Kan., to Miss Jean L. Knablein of Erie, Pa., August 9.

Ralph Eichhorn, New York, to Miss Fredell Lack at La Porte, Texas, July 10.

Deaths

Charles Sumner Bacon ⊕ Chicago; born in Spring Prairie, Wis., July 30, 1856; Chicago Medical College, 1884; professor of obstetrics from 1903 to 1913, professor of obstetrics and head of the department of obstetrics, 1913-1914, and of obstetrics and gynecology, 1914 to 1926, at the University of Illinois College of Medicine, where the Bacon lectures were named in his honor and where since 1926 he had been emeritus professor of obstetrics and gynecology; formerly professor of obstetrics at the Chicago Policlinic; chairman of the Section on Obstetrics and Diseases of Women, 1905-1906, of the American Medical Association, of which he was an Affiliate Fellow; past president of the Chicago Medical Society and the Chicago Gynecological Society; fellow of the American Association for the Advancement of Science and the American College of Surgeons; member of the Chicago Pathological Society, Institute of Medicine, Chicago Society of Medical History and the Chicago Academy of Sciences; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; author of "Obstetrical Nursing"; chief of staff, Booth Memorial Hospital; consulting gynecologist at the City of Chicago Municipal Sanitarium; consulting obstetrician at the Grant Hospital, where he died July 10, aged 90, of bronchopneumonia and myocarditis.

William John Carrington ⊕ Clinton, Iowa; born in Jefferson City, Mo., in 1884; Jefferson Medical College of Philadelphia, 1908; vice president of the American Medical Association, 1942-1943; member, past president and corresponding secretary of the Medical Society of New Jersey; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; fellow of the American College of Surgeons; past president of the Jefferson Medical Alumni Association; served during World War II; past president of the school board in Ventnor City and the Kiwanis International; formerly practiced in Atlantic City, N. J., where he had been affiliated with the Atlantic City Hospital and the Municipal Hospital; formerly on the staff of the Pine Rest Hospital in Northfield, N. J.; head of the surgical service of the Schick General Hospital; died July 24, aged 63, of carcinoma.

Hugh Kling Berkley ⊕ Beverly Hills, Calif.; born in Woodbine, Ia., in 1889; University of California Medical School, San Francisco, 1914; associate clinical professor of pediatrics at the University of Southern California School of Medicine, Los Angeles; specialist certified by the American Board of Pediatrics; served during World War I; member of the American Academy of Pediatrics; past president of the Southwestern Pediatric Society; on the staffs of the Los Angeles Children's, St. Vincent's, Hollywood Presbyterian, Cedars of Lebanon and California Lutheran hospitals as well as the Good Samaritan Hospital, where he died July 11, aged 57, of cerebral hemorrhage and arteriosclerosis.

Albert O. Singleton ⊕ Galveston, Texas; born in Mount Peak, Texas, July 16, 1882; University of Texas School of Medicine, Galveston, 1910; professor of surgery and chairman of the department at his alma mater; member of the founders group of the American Board of Surgery; served as president of the Texas Surgical Society and as vice president of the American College of Surgeons, of which he had been a fellow; member of the American Surgical Association, Southern Surgical Association; American Association for the Surgery of Trauma and the American Association for Thoracic Surgery; surgeon in chief of the John Sealy Hospital; died June 12, aged 64, of coronary thrombosis.

Parker Garfield Borden, Canandaigua, N. Y.; University of Buffalo School of Medicine, 1904; member of the American Psychiatric Association and the American Medical Association; served during World War I; formerly clinical director of the Veterans Administration Hospital and chief neuropsychiatrist of the Buffalo regional office of the Veterans Administration; at one time affiliated with the Veterans hospitals at Palo Alto, Calif., Philadelphia and Northampton, Mass.; formerly surgeon for the U. S. Public Health Service; died in the Buffalo General Hospital July 4, aged 68, of heart disease.

David Clare Budge, Logan, Utah; born in Paris, Idaho, Sept. 27, 1873; also a dentist; Rush Medical College, Chicago, 1900; for many years president of the state board of medical examiners; past president of the Utah State Medical Association and the Cache Valley Medical Society; fellow of the American College of Surgeons; member of the American Medical Association; for many years medical director of the William Budge Memorial Hospital; director of the First Security Corporation; died June 21, aged 73, of cardiorenal disease.

Howard S. Allen ⊕ Woodbury, Conn.; Yale University Medical School, New Haven, 1904; medical examiner and health officer of Woodbury; for many years member of the board of education; died in the Woodbury Hospital July 5, aged 65, of uremia.

John Vincent Allen Jr., Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1917; member of the American Medical Association; served overseas during World War I; died in the Hahnemann Hospital June 28, aged 52, of congestive heart disease.

Harry Burgwyn Baker, Richmond, Va.; University College of Medicine, Richmond, 1900; died June 14, aged 78, of arthritis.

Llewellyn Edwin Barnes, Chicago; Reliance Medical College, Chicago, 1910; member of the American Medical Association; on the staff of the Evangelical Hospital; died in Hammond, Ind., July 23, aged 68, of cerebral hemorrhage.

Jesse A. Bates, Oklahoma City; St. Louis College of Physicians and Surgeons, 1923; on the staffs of the Wesley and Polyclinic hospitals; died June 30, aged 58, of coronary occlusion.

Felix J. Baur, Milwaukee; Chicago College of Medicine and Surgery, 1915; member of the American Medical Association; for many years fire department surgeon; on the staff of St. Anthony's Hospital; died in Ashland, Wis., July 2, aged 55, of coronary thrombosis.

Francis Clayton Bennett ⊕ Monroe, La.; University Medical College of Kansas City, Mo., 1900; served one term as a representative in the state legislature; past president of the Louisiana State Medical Society and the Ouachita Parish Medical Society; fellow of the American College of Surgeons; affiliated with St. Francis and Conway Memorial hospitals; died June 27, aged 77, of heart disease.

Irvin H. Betts ⊕ Visalia, Calif.; University of California Medical School, San Francisco, 1915; past president of the Tulare County Medical Society; served as a medical officer in Siberia during World War I; affiliated with the Visalia Municipal Hospital; died in San Francisco July 1, aged 58, of aortic stenosis.

Robert Le Roy Browning, Pawnee, Okla.; Birmingham Medical College, 1911; member of the American Medical Association; served during World War I; on the staff of the Pawnee Municipal Hospital; died in the Enid (Okla.) General Hospital June 15, aged 64, of abscess of the liver following resection of the stomach.

Calvin E. Carney, Delphi, Ind.; Medical College of Indiana, Indianapolis, 1895; member of the American Medical Association; president of the city board of health; died in the Methodist Hospital, Indianapolis, July 3, aged 79, of coronary thrombosis.

Charles Augustus Carpenter, Caldwell, N. J.; Baltimore Medical College, 1909; member of the American Medical Association; police surgeon for both the Caldwell and West Caldwell police departments; died July 6, aged 68, of carcinoma of the prostate.

Elias Howell Cross Jr., Gadsden, Ala.; Vanderbilt University School of Medicine, Nashville, 1926; member of the American Medical Association; served during World War I; affiliated with the Holy Name of Jesus Hospital; died June 22, aged 48, of cardiac thrombosis.

Russel Oscar Davidson, Buffalo; Hahnemann Medical College and Hospital of Philadelphia, 1923; served during World War I; on the staff of the Millard Fillmore Hospital; died in the U. S. Marine Hospital June 13, aged 49, of Laënnec's cirrhosis.

Leo Joseph Doll, Buffalo; University of Buffalo School of Medicine, 1899; member of the American Medical Association; died in the Edward J. Meyer Memorial Hospital June 4, aged 69, of arteriolar nephrosclerosis and bronchitis.

Douglas Shearer Duncan, Peoria, Ariz.; Fort Worth School of Medicine, Medical Department of Fort Worth University, 1912; served during World War I; for many years affiliated with the Indian Service; died June 13, aged 56, of heart disease.

Frank Kingsley Dutton ⊕ Springfield, Mass.; Tufts College Medical School, Boston, 1915; fellow of the American College of Surgeons; for many years affiliated with the Springfield Hospital; died at Ten Mile Lake, Minn., June 28, aged 55, of coronary thrombosis.

Amelia Levinson Gates, San Francisco; Cooper Medical College, San Francisco, 1894; died in Carmel, Calif., June 2, aged 81, of hypertensive cardiovascular disease.

Thomas Edmund Peachey Gocher, San Rafael, Calif.; University of Toronto Faculty of Medicine, Toronto, Canada, 1915; member of the American Medical Association; died June 22, aged 56, of uremia.

Charles Howard Halverstadt ⊕ Perrysville, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1899; died June 15, aged 77, of heart disease.

Levi A. Harris, Gaylord, Mich.; Detroit Medical College, 1884; member of the American Medical Association; past president of the Otsego, Montmorency, Crawford, Oscoda, Roscommon and Ogemaw Counties Medical Society; died in the Mercy Hospital, Grayling, June 24, aged 88, of heart disease.

George David Hauberg ⊕ Moline, Ill.; Northwestern University Medical School, Chicago, 1911; past president of the Rock Island County Medical Society and of the Iowa and Illinois Central District Medical Association; on the staffs of the Moline Lutheran and Public hospitals; died June 23, aged 63, of carcinoma of the prostate.

Hezekiah Haws, Warfield, Ky.; Kentucky School of Medicine, Louisville, 1903; died in Matewan, W. Va., June 26, aged 73, of injuries received when his jeep was struck by a railroad train.

Howard Clifford Hyndman ⊕ Cincinnati; Medical College of Ohio, Cincinnati, 1909; died in the Christ Hospital June 25, aged 64, of auricular ventricular block.

Frederick Gibson James ⊕ Greer, S. C.; University of Tennessee Medical Department, Nashville, 1894; died in the General Hospital, Greenville, June 20, aged 75, of cerebral embolus.

William Henry Lake, Jackson, Mich.; Northwestern University Medical School, Chicago, 1910; member of the American Medical Association; served during World War I; on the staffs of the W. A. Foote Memorial and Mercy hospitals; died in Traverse City June 24, aged 62, of coronary infarction.

John Aden Lewis Sr., New Orleans; Tulane University of Louisiana School of Medicine, New Orleans, 1915; instructor in medicine at his alma mater; member of the American Medical Association; on the staffs of the Baptist and Charity hospitals; died June 24, aged 65, of coronary disease.

Holton Murschamp Lowe ⊕ Battle Creek, Mich.; University of Michigan Medical School, Ann Arbor, 1916; past esident of the Calhoun County Medical Society; on the affs of the Community Hospital and the Leila Y. Post Montgomery Hospital, where he died June 21, aged 71, of uremia.

Curtis Carl McMackin, Springfield, Ill.; Missouri Medical College, St. Louis, 1895; died in the Memorial Hospital June 20, aged 89, of a fractured hip received in a fall.

Charles W. Meriwether, Pomona, Calif.; St. Louis College of Physicians and Surgeons, 1898; died May 21, aged 81.

Harold Faulkner Miller ⊕ Louisville, Ky.; University of Louisville School of Medicine, 1925; died June 19, aged 45, of coronary occlusion.

William J. Miller, La Valle, Wis.; Milwaukee Medical College, 1902; formerly member of the state board of health; died in Madison June 16, aged 77, of prostatic hypertrophy and acute pyelonephritis.

Robert Edgar Miltenberger ⊕ Spring Valley, Ill.; Rush Medical College, Chicago, 1910; fellow of the American College of Surgeons; served during World War I; health officer; past president of the Bureau County Medical Society; on the staff of St. Margaret's Hospital; died June 18, aged 67, of coronary occlusion.

Samuel B. Moore, Tucapau, S. C.; Medical College of the State of South Carolina, Charleston, 1910; died in the General Hospital, Spartanburg, June 23, aged 64, of an injury received in a fall.

George Burr Morris, Bluffton, Ind.; Indiana Medical College, School of Medicine of Purdue University, Indianapolis, 1906; for many years city health officer; served during World War I; major, medical reserve corps, U. S. Army, not on active duty; died June 17, aged 67, of coronary occlusion.

Charles Thomas Osterloh, Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1901; member of the American Medical Association; veteran of the Spanish-American War; medical examiner for the draft boards during World War I and World War II; on the staffs of St. John's Hospital and the Allegheny General Hospital, where he died June 20, aged 71, of carcinoma of the cecum.

Ralph Ernest Pond, Meadville, Pa.; Homeopathic Hospital College, Cleveland, 1892; died in the City Hospital June 1, aged 79, of chronic myocarditis.

Albert Sensabough Powe, Cranston, R. I.; Eclectic Medical Institute, Cincinnati, 1890; Tufts College Medical School, Boston, 1899; died June 14, aged 83, of carcinoma.

Emil Camille Robitshek ⊕ Minneapolis; University of Minnesota College of Medicine and Surgery, Minneapolis, 1903; clinical assistant professor of surgery at his alma mater; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons; past president of the Minnesota Surgical Society; on the staffs of the Abbott Hospital and the Eitel Hospital, where he died June 23, aged 66, of lymphosarcoma.

James Arthur Rowley ⊕ Flint, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1903; served on the staff of the Hurley Hospital, where he died June 22, aged 72, of cerebral hemorrhage.

Moses Victor Safford, Boston; Medical School of Maine, Portland, 1893; member of the American Medical Association; served as a surgeon in the immigration service, with the U. S. Public Health Service and as deputy health commissioner of Boston; at one time epidemiologist of the city health department; died June 20, aged 79, of carcinoma of the prostate.

William Frederick Schroeder ⊕ Rock Island, Ill.; University of Minnesota Medical School, Minneapolis, 1926; past president of the Rock Island County Medical Society; served overseas during World War I; examining physician for a draft board during World War II; fellow of the American College of Physicians; served as chief of staff of St. Anthony's Hospital, where he died June 10, aged 61, of acute leukemic reticuloendotheliosis.

Oliver William Shellem, Denver, N. C.; North Carolina Medical College, Charlotte, 1909; died in Asheville June 10, aged 60, of arteriosclerosis and uremia.

Arthur William Sieker ⊕ Plymouth, Wis.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1900; died in St. Nicholas Hospital, Sheboygan, June 19, aged 73, of mitral stenosis.

Henry Stempa ⊕ Wethersfield, Conn.; Friedrich-Wilhelms-Universität-Medizinische Fakultät, Berlin, Prussia, 1898; died in the Hartford Hospital June 12, aged 68, of cerebral hemorrhage.

Robert Allan Stimpson, Detroit; Detroit Homeopathic College, 1907; formerly on the staff of the Grace Hospital; died June 13, aged 68, of multiple arthritis.

Edward Clark Streeter, Stonington, Conn.; Northwestern University Medical School, Chicago, 1901; curator of the museum collections of Yale Medical Library and formerly visiting professor of the history of medicine at the Yale University Medical School in New Haven; died June 17, aged 72, of coronary disease.

Robert Edward Trout, Oaktown, Ind. (licensed in Indiana in 1904); died June 19, aged 91, of myocarditis.

Arthur John Walscheid ⊕ North Bergen, N. J.; Dartmouth Medical School, Hanover, N. H., 1897; formerly adjunct professor of gynecology at the New York Polyclinic Medical School and Hospital, New York; affiliated with the North Hudson Hospital in Weehawken, where he died June 14, aged 72, of pulmonary embolism.

Todd Pope Ward ⊕ Mount Vernon, Ill., Jefferson Medical College of Philadelphia, 1903; served during World War I; died in the Good Samaritan Hospital June 9, aged 66, of cerebral hemorrhage.

Robert Francis Weaver, St. Clair, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1907; member of the American Medical Association; served as an officer during World War I; an examining physician for a draft board during World War II; chief gynecologist at the Pottsville (Pa.) Hopital; died in the Mayo Clinic, Rochester, Minn., June 23, aged 63, of cardiac failure and paralytic ileus.

Albert Andrew Weber, Bessie, Okla.; Rush Medical College, Chicago, 1903; member of the American Medical Association; died May 21, aged 69, of endocarditis.

Richard J. Williams, Dunning, Neb.; Western University Faculty of Medicine, London, Ont., Canada, 1895; died in Ansley May 15, aged 76, of chronic myocarditis.

John W. Wills, Weslaco, Texas (licensed in Texas, under the Act of 1907); died June 2, aged 78, of coronary thrombosis.

James Melvin Young, Jefferson, Iowa; Omaha Medical College, 1898; died May 15, aged 77, of coronary occlusion.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Aug. 16, 1946.

The Outbreak of Infantile Paralysis

The outbreak of infantile paralysis continues. In London there are now 165 suspected or confirmed cases in the hospitals, and fresh cases and deaths are reported daily from various parts of the country. The twelve London teaching hospitals are opening units for the treatment of acute cases. In some hospitals the patients will be treated in isolation wards, with special medical and nursing staffs. Elsewhere they will be admitted to the general wards and nursed with special "barrier" technic which eliminates risk to other patients. As a precaution against infection, functions which bring children together, such as school camps, are being canceled and the use of swimming pools is being forbidden to children under 14.

The World Federation of Pathologists

The European Association of Clinical Pathologists has met at Cambridge under the presidency of Dr. S. C. Dyke and reconstituted itself as a world federation of societies devoted to clinical pathology. The federation has defined its aims as (1) to develop clinical pathology—the application of pathology and allied sciences to medicine, (2) to have regard to the scientific and professional status of those engaged in its practice and (3) to foster international amity. A committee was appointed to call a meeting of delegates from as many interested associations as possible next November in Paris during the meeting of the French Société de biologie clinique to formulate a constitution and elect officers. The federation hopes to gain worldwide membership and invites societies devoted to clinical pathology to communicate with the secretaries—either Dr. W. H. McMennemy, pathologic department, Royal Infirmary, Worcester, England, or Dr. J. Ungar, Glaxo Laboratories, Greenford, Middlesex, England. The Czechoslovak Association of Clinical Pathologists, the French Société de biologie clinique and the Association of Clinical Pathologists of Great Britain have already signified their wish to join the federation. Medical practitioners or university graduates practicing clinical pathology who are members of the constituent bodies will thereby become members of the federation. Membership will be available also to those who are eligible but do not belong to a constituent body. The federation proposes to hold a conference at least once every three years at the same time and place as the summer meeting of one of its constituent bodies. It hopes that the first meeting will take place in the summer of 1948.

The Training of Clinical Pathologists

In January the Association of Clinical Pathologists appointed a committee to consider the training and definition of consultants in clinical pathology—a recently constituted specialty. The committee has recommended that five years after the pathologist has qualified in medicine should be devoted to gaining further clinical experience (one year), working in a university department (one year) and working in a department of clinical pathology (two years). In the remaining year the student should extend his experience as he wishes. The object in working in a university department is to train the student in scientific method and to introduce him to an atmosphere where research is being vigorously pursued. The committee also suggests that students should be encouraged to take a diploma in bacteriology or in clinical pathology. While working in a department of clinical pathology in a large hospital or a group laboratory the student should receive training in all branches of pathology, which should include hematology, bacteriology, chemistry and morbid anatomy. The committee recommends that a special committee be set up to approve laboratories suitable for training. Students who have obtained a first or second class science degree—for example, in physiology or in chemistry—or a doctorate in philosophy should be eligible for recognition as specialists in four instead of in five years.

The committee recognizes that these criteria cannot necessarily be applied to existing clinical pathologists or to some of those in training. It therefore advocates that specialists at present recognized should have been registered for a minimum of five years and have had at least four years' laboratory experience. They should also hold a higher medical or scientific qualification or have contributed to the advance of medical or scientific knowledge. In accordance with a decision of the Royal College of Physicians the committee does not think that a register of specialists in clinical pathology should be compiled. Because of the financial support that these years of training necessitate and the lack of which debars poorer students from undertaking them, the committee quotes the recommendation of the committee on neurology of the Royal College of Physicians that suitable candidates for the specialty should be supported by scholarships, government grants or otherwise.

A Photographic Display of Venereal Diseases

At the request of the Ministry of Health, the Central Office of Information is making a new approach to the problem of preventing venereal disease. They are to show the venereal diseases photographic display set to factories and other managements employing over 500 people. This request has been made in view of recent figures of venereal diseases, which show an increase on the wartime figures, which already were an increase on the peacetime ones. The exhibition was produced for the Ministry of Health with the cooperation of the Central Council for Health Education. It was offered in 1945 to factories and local authorities on free loan. So far it has been borrowed by 155 factories and 53 local authorities. Reports from the factories show that it was well received, the most frequent commentary being that it should have been made available earlier. This was heard most frequently from the younger generation, who were made to realize the serious effects of infection.

Air Travel Health Problems

The Ministry of Health is exercised by the ever increasing health problems of airports. One example is an outbreak of smallpox due to two soldiers who arrived by air from Naples and sickened from the disease. As a result there were 4 secondary cases in this country, all in unvaccinated persons. These were the only cases that originated in 1945. A third case reached England on December 9 from India. The patient was ill when he arrived, but no secondary cases occurred. Surveillance of air passengers is unusually difficult. Those arriving from abroad are now handed a card on which a notice is printed in French and English warning them that they may have been in contact with some infectious disease without knowing it. They are urged, if they fall ill within twenty-one days of arrival, at once to consult a doctor and show him the card.

International Physiologic Congress

More than a thousand delegates from thirty-six countries have assembled at Oxford for the seventeenth International Physiological Congress, the first to be held since the war. At the opening plenary session the chair was taken by Sir Henry Dale, F.R.S., biochemist and pharmacologist. The program includes over 350 scientific communications, 75 demonstrations and 50 films. Much of the new knowledge discussed was the result of war research, such as Professor J. B. S. Haldane's discoveries on the action of high pressure oxygen in man and those of an American team on the effects of tight turns in airplanes on

Correspondence

VITAMIN D THERAPY IN ARTHRITIS

To the Editor:—I read, with great interest, the report on Vitamin D poisoning by Dr. Kaufman et al. in THE JOURNAL June 21. I should like to register my reactions to this article, both as to possible cause of death and to the manner in which it was presented for publication.

There is no doubt in my mind that the metastatic deposits mentioned in the report were due to vitamin D intoxication. Several valid cases are on record, and I have had 1 case (in ten years' study at the Arthritis Clinic at the Hospital for Special Surgery) which definitely followed the overzealous use of vitamin D preparations. However, I do not believe the Kaufman case is a clearcut instance of renal failure due to vitamin D intoxication. For instance, the patient had, according to the history, one hundred injections of gold. (If a small dose of only 5 mg. of gold was given at each injection—the average dose being 50—over 5 Gm. of gold would have been injected into the patient in two years.) It is well known that gold preparations are not entirely excreted, but could remain in the body for many months—even years. This could well explain the five months' pruritus she complained about prior to her last admission, since gold preparations are much more likely to produce itching than vitamins.

In this report, as well as all other papers dealing with vitamin D poisoning, mention is never made regarding any beneficial results from vitamin D. It seems strange that any patient would take Ertron for fourteen months without some relief.

The report was written by an author who had never used vitamin D in treating arthritis. Apparently the author had little to do with the treatment or observation of this patient, because many inaccuracies in reporting otherwise would not have been made. For instance, in describing the physical examination, it mentions a chronically ill "middle aged" woman, yet her given age was 65. Then the differential blood count is given as 77 per cent polys, 12 per cent lymphocytes, 4 per cent monocytes and 1 per cent eosinophils, a total of only 94 per cent of the cells being accounted for. Also the urine is described as being clear, yellow, alkaline, specific gravity 1.012, albumin 2 plus, sugar 1 plus, and epithelial cells in the sediment. (How can urine be clear and have a sediment?)

Then, it is stated, "The abscesses were not real abscesses," and then it is said, "Penicillin therapy was started because of the presence of Staphylococcus aureus in the culture." (Why wouldn't they be real abscesses if they contained staphylococci?)

A blood calcium of 147 mg. per hundred cubic centimeters is described, and one week later the calcium level was 130 mg. Is it possible that this could be a typographic error, since the highest calcium seen in our clinic was 20 mg. per hundred cubic millimeters, and this was considered doubtful by our laboratory?

A colloid cyst of the parathyroid is described in the autopsy findings. Could this have in any way contributed to the vast degree of calcium deposits along with the Ertron?

WILLARD H. SQUIRES, M.D.,
40 East 61st Street,
New York.

(With reference to the blood calcium mentioned in the preceding letter, a decimal point was omitted. The figures should read 14.7 and 13.0 mg., respectively. A correction to this effect was published in THE JOURNAL, July 12, page 971.—ED.)

PAINFUL PHANTOM FOOT

To the Editor:—In an article entitled Abolition of Painful Phantom Foot by Resection of the Sensory Cortex, by Drs. Echols and Colcough, which appeared in the August 23 issue of THE JOURNAL the statement appeared "He continued to complain of numbness and pain, however, and in October 1943 requested that his leg be amputated. Though the foot was fairly warm, amputation seemed advisable on the basis of the excruciating pain."

I should like to take issue with these statements. I do not believe that a patient's request should serve as an indication for amputation nor do I feel that excruciating pain, of itself, in a warm foot should be considered an indication for amputation.

A procedure much less formidable is available for the treatment of such excruciating rest pain. Smithwick and White in 1930 and Laskey and Silbert in 1933 advocated the relief of such pain either by the injection with alcohol of the sensory nerves supplying the foot (Smithwick and White) or by the section of the peripheral nerves of the foot (Laskey and Silbert). The appearance of a patient following the section of the sensory nerves is one of the most satisfying experiences. The change from a despondent person who has not slept for weeks and who demands amputation is dramatic. There is immediate relief from pain.

One wonders whether section of the nerves in Drs. Echols and Colclough's patient might not have avoided an amputation and the subsequent resection of the sensory cortex, with its train of unpleasant complications.

M. J. KUTISKER, M.D.
Peripheral Vascular Clinic,
New York University College of Medicine,
New York 16.

GLAUCOMA

To the Editor:—I believe most ophthalmologists would have difficulty in concurring with the opinions expressed in answer to the request for a description and treatment of glaucoma which appeared in Queries and Minor Notes (THE JOURNAL, p. 1515) of Aug. 23, 1947. While it is certainly difficult, if not impossible, to answer satisfactorily such questions in the space ordinarily available, there is nevertheless serious doubt as to the accuracy of the statements given. To limit the discussion to so-called chronic simple glaucoma was, undoubtedly, a reasonable plan, but the reply could have comprised somewhat more.

The authority quoted may well have meant what is pathetically true in the case of many persons with chronic simple glaucoma when he indicates, "serious loss of vision before the patient knows of any trouble at all." But there are often other well known and even almost distinctive clues that this misfortune is at hand, such as fulness of the eyes or head, headache, poor acuity in reduced illumination and frequent or unsatisfactory changes in lenses.

Mention of field changes, while their determination is a subjective test, hardly is to be considered a symptom unless there has been such progression of the disease as to cause difficulty because of reduction of the peripheral visual field. At that time, one scarcely speaks of early glaucoma. Contrary to the expressed notion, moreover, is the fact that the earliest central field change is not an enlargement of the blind spot, but rather ". . . depression with peripheral contraction, more pronounced on the nasal side, associated with a nasal step

. . . depression of the upper part of the central field between the blind spot and the horizontal meridian to the nasal side of the fixation point. As a rule, this depression is most manifest near the blind spot, constituting baring of the blind spot" (Traquair, H. M.: An Introduction to Clinical Perimetry, ed. 4, St. Louis, C. V. Mosby Company, 1944).

The statement which could seem to be open to the greatest doubt is the one indicating uniformly successful operative treatment. To begin with, I believe it would be hard to find any ophthalmologist who in any way would regard any of the glaucoma operations always successful, in the hands of any surgeon. The selection of operation is, as it always has been, a difficult choice, guided by many findings. Functional loss, as represented by field changes, provides the index of damage. Progression of these changes, whatever their extent originally, indicates usually the failure of the treatment then being utilized, and this even in the face of lower tensions as expressed by the tonometer. It is certainly safe to assume that there will be failures, and there are even some of us who are occasionally driven to wonder if there is any operative success.

One must assume that by control of "low tensions" by the miotics mentioned, it is meant the lower of the proved pathologically elevated intraocular pressures for the particular eye or eyes. At present, of course, there are two or three possibly clinically useful miotics other than those mentioned.

I presume that the word "iridodenclesis" was intended to be iridencleisis.

S. N. Key Jr., M.D., Austin, Texas.

RECTAL COMPLICATIONS OF EPISIOTOMY

To the Editor:—In the article on Rectal Complications of Episiotomy on page 1174 of The Journal, August 2, Marbury and Goldman do not state the type of episiotomy which was performed, but I judge that it was the old median episiotomy. It is only right to call the attention of the profession to the fact that a mediolateral episiotomy, or perineotomy, will avoid the dangers and complications which are portrayed in this article, since the incision avoids the close neighborhood of the rectum. Over many years I have never seen this type of perineotomy give any subsequent trouble. Instead of the incision being in the line between the posterior fourchette and the anus, it is made from the point a little to the right or left of the posterior fourchette and runs obliquely outward. While the occasional operator may find it advantageous to have his index finger in the rectum when putting in the sutures, this is unnecessary if the operator has had a modicum of experience, since he is far enough away from the rectum to avoid the danger of its perforation with the needle.

William R. Nicholson, M.D., Philadelphia.

IMMUNITY IN SYPHILIS

To the Editor:—With regard to your editorial "Immunity in Syphilis" (The Journal, August 23, p. 1485), may I call attention to my paper "Semantic Confusion and Resolution in the Concepts of Cure in Syphilis and of Reinfection With Syphilis," which was published in the *American Journal of Syphilis, Gonorrhea and Venereal Diseases* (30:344 [July] 1946). This article covers much the same ground as your editorial and appeared in point of time between the paper of Moore and that of Urbach and Beerman, which you cite. My interpretations of the clinical events of syphilis and of allergic and immunologic theory as related to the disease are somewhat different from those of the writers cited. It may be of interest to readers to examine this version together with the references given.

Morris Leider, M.D., Brooklyn.

Medical Motion Pictures

FILM REVIEWS

Transthoracic Resection for Carcinoma of the Cardiac End of the Stomach. Prepared in 1946 by Herbert R. Hawthorne, M.D., Graduate Hospital, University of Pennsylvania. 16 mm., color, silent, 650 feet (two reels). Showing time twenty-five minutes. Procurable on loan from the Author, University of Pennsylvania, 19th and Lombard streets, Philadelphia.

The author obtains exposure by resection of the eighth rib on the left, retraction of the lung and incision of the diaphragm. The lower end of the esophagus and upper portion of the stomach are mobilized and resected. The remaining portion of stomach is closed, with the formation of a tubular structure which is brought up to meet the end of the esophagus and an opening made in the stomach. Two inner rows of catgut and one outer row of interrupted silk are used for the anastomosis. The stomach is anchored to the parietal pleura to prevent traction on the suture line. The diaphragm is closed with interrupted silk around the upper portion of the gastric stump. The thorax is closed after insertion of a catheter leading down to a basin of water.

The photography in this film is good; exposure is adequate at all times to allow proper visualization of the operative procedure. The technic is good; the only criticism which might be offered is that the author might have used more gauze packs around the site of operation to minimize contamination.

Sterility, Its Causes, Investigation and Treatment. Prepared by Samuel L. Siegler, M.D. Produced in 1944 by the Bergman Association, New York. 16 mm., color, silent, 1,600 feet (one reel). Showing time fifty minutes. Procurable on loan from Samuel L. Siegler, M.D., 706 Eastern Parkway, Brooklyn.

This film presents a large amount of factual material related to the problem of sterility in men and women; the most valuable things in it are living pictures of various types of patients and some details of treatment. The important parts would probably make a film of one third the present length. The rest is largely an array of subtitles intended to make the film useful in teaching. This portion in its present form is so grossly defective as to spoil the film for any purpose whatever. It employs mystifying or undignified abbreviations like SDA, HP and TB, uses "hypospadia" as if it were the singular of "hypospadias," uses "media" for "medium," writes "azospermia" for "azoospermia," spells the name "Froehlich" several ways but always wrong, uses "cornua" as if it were the singular form, uses the phrase "Levi-Lorraine" as if everybody already knew what it meant (whereas it is not to be found in the twentieth edition of Dorland's Medical Dictionary) and is in general calculated to introduce confusion into some teacher's carefully organized course. Methods of treatment are named as having been "used" without indicating whether they were found salutary or ruinous. The age of the patient is essential in interpreting the case histories but is rarely given if ever; it is particularly important considering that the author recommends treatment for sterility if one year of married life has elapsed without conception and ignores what is now known about physiologic sterility of adolescence. It is doubtful whether many clinicians would speak so confidently about the advantages of vitamin E in human subjects, the value of the "implantation" operation, and the use of the potentiometer in detecting the time of ovulation.

The film certainly would prove confusing to an audience of American medical students.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Employer's Liability for Negligence of Its Medical Staff.—The plaintiff sued for damages alleged to have resulted directly from the failure of the defendant's medical staff to make a proper examination and diagnosis of his injuries. From a judgment in favor of the defendant the plaintiff appealed to the United States Circuit Court of Appeals, Fifth Circuit.

The defendant maintained a medical staff and clinic to which its employees were required to report whenever they were injured. While in the performance of his duties as a mechanic, the plaintiff sustained an injury to his back and, on notifying his foreman, was immediately directed to report to the clinic There he was examined by a member of the medical staff who was a physician and an employee of the defendant. The physician stated that, in his opinion, the injuries were not serious and directed the plaintiff to continue his work, which was of a heavy character; at that time, however, unknown to the plaintiff, his back was actually broken. Following the accident, plaintiff suffered excruciating pains in his back but, although he reported his suffering to the clinic, no x-rays were taken, notwithstanding plaintiff requested that this be done, and no effort was made to diagnose his injury properly and correctly, the same being dismissed as of no moment by the defendant's employees. Having a wife and child to support, and in reliance on the advice and direction of the defendant, the plaintiff continued to work although his broken back constantly caused him great pain and suffering. Knowing plaintiff's condition, insofar as the symptoms were concerned, the defendant in June 1943 directed him to carry a large and cumbersome bundle of metal from one place to another in the shop. While he was endeavoring to do so the weight shifted and the plaintiff was compelled to catch the bundle in an unbalanced position. Immediately he felt a stinging pain in his left groin. Thinking that he had ruptured himself, the plaintiff again reported to the clinic maintained by the defendant. No regular physician was present at the time, and he was seen by a first aid man who, on examination, stated that there was a lump in plaintiff's left side. He was later seen by a physician employed by the defendant who instructed him to return to work but to refrain from lifting any heavy loads for the time being. This physician advised the plaintiff that he was not ruptured and that in a few days he would have no further trouble with his groin. During all of this time, plaintiff suffered day and night from his back. Thereupon, plaintiff obtained a leave of absence and went to a hospital in Vicksburg, Miss., where a thorough examination immediately disclosed that his back was broken and that he was ruptured. He was promptly operated on for his rupture, and a brace was applied to his back.

The defendant contends that an employer is not liable for the erroneous diagnosis or negligent treatment of an employee's ailment by one of its physicians, where the employer was not negligent in selecting the physician and had no knowledge of his incompetence, such physician having a good reputation. Such a rule, said the court, is not absolute in Mississippi, although in some circumstances the master is not liable for the negligence or unskilfulness of a physician employed by him, provided he has exercised due care in selecting the physician. There was nothing in the complaint to warrant the inference in this case that the master employer undertook gratuitously to furnish the plaintiff medical assistance and was bound only to exercise reasonable care in the selection of the physician. On the contrary, it is reasonable to infer that the defendant established the clinic and employed the members of the medical staff for its own ends and purposes, thereby constituting the physician in charge his agent. Reporting to the clinic was not optional. The rules and regulations of the company, which plaintiff was instructed to obey, required him to report to a clinic in charge of a physician employed by the defendant. Not only that, the foreman specifically ordered him to report in this instance. He obeyed this order and was injured by the negligence of the physician in charge, who represented the defendant and was neither selected nor employed by the plaintiff. The fact that no charge was made against the plaintiff, or fee paid, for the doctor's services is not controlling. Every branch of a business need not be directly remunerative in order to warrant its maintenance for pecuniary reasons.

As to this physician and his treatment of plaintiff, the doctrine of respondeat superior applies. The defendant contends that the nature of the physician's vocation prohibits the application of this doctrine We know of no public policy against its application, said the court. Physicians and surgeons, in undertaking the duties of their profession, impliedly warrant that they are possessed of the requisite skill, learning and technical training to do the work required of them. The personal liability of the doctor must not be confused with that of his employer. The doctor's liability remains the same whether or not his employer also is liable. The principal is responsible for the tort of his agent, not because the former has done wrong, but because the law so declares as a matter of public policy. There is no more reason to except employers of physicians from the doctrine of respondeat superior than there is to except employers of other highly skilled persons who perform technical services requiring discretion. Whether the doctor was acting for any one other than himself when he committed the tort, and if so for whom, are questions of fact unless the facts are undisputed and conflicting reasonable inferences may not fairly be drawn theretrom. Accordingly the judgment in favor of the defendant was reversed and the cause remanded to the trial court for further proceedings.—*Knox v. Ingalls Shipbuilding Corporation, 158 F. (2d) 973 (1947).*

COMING EXAMINATIONS AND MEETINGS

BOARDS OF MEDICAL EXAMINERS
BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of the boards of medical examiners and boards of examiners in the basic sciences were published in The Journal Sept. 20, page 181.

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Part III.* Durham, N. C., Oct. 21-23. Exec. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia 2.

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: Part II. *Oral.* Cleveland, Oct. 5-11. Sec., Dr. P. M. Wood, 745 Fifth Ave., New York 22.

American Board of Internal Medicine: *Oral.* Chicago, Oct. 8-10. Asst. Sec., Dr. W. A. Werrell, 1 West Main St., Madison 3.

American Board of Neurological Surgery: *Oral.* Chicago, May or June. Final date for filing application is Feb. 1. Sec., Dr. W. J. German, 310 Cedar St., New Haven, Conn.

American Board of Obstetrics and Gynecology: *Part I. Written.* Various Centers, Feb. 6. Final date for filing application is Nov. 1. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh 6.

American Board of Ophthalmology: Chicago, Oct. 6-12. Sec., Dr. S. Judd Beach, 704 Congress St., Portland, Me.

American Board of Orthopaedic Surgery: *Part I.* Applications are accepted for the next examination until Jan. 15, 1948.

American Board of Otolaryngology: Chicago, Oct. 7-11. Sec., Dr. D. M. Lierle, University Hospitals, Iowa City.

American Board of Pathology: *Oral and Written. All Groups.* Applications are accepted for the next examination until Oct. 1, 1947. Sec., Dr. Robert A. Moore, 507 Euclid Ave., St. Louis.

American Board of Pediatrics: Dallas, Dec. 5-7. Philadelphia, Jan 9-11. Sec., Dr. Lee F. Hill, 718 Royal Union Bldg., Des Moines 9.

American Board of Plastic Surgery: Examinations are given in April and November of each year in the home town of applicants. Sec., Dr. Robert H. Ivy, 1930 Chestnut St., Philadelphia.

American Board of Surgery: *Written.* Various Centers, March. Final date for filing application is Dec. 1. Sec., Dr. J. S. Rodman, 225 S. 15th St., Philadelphia 2.

American Board of Urology: Chicago, February. Final date for filing application is Nov. 1. Sec., Dr. Harry Culver, 1409 Willow St., Minneapolis 4.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Comparative Study of Intracavity Potential in Man and in Dog. D. S. Pallares, M. Vizcaino, J. Soberon and E. Cabrera.—p. 819.

Weight of Red Blood Corpuscles in Heart Failure Determined with Labeled Erythrocytes.—Nylin and Hedlund say that the Hevesy method for labeling blood corpuscles with radioactive phosphorus has contributed greatly to the study of different problems of circulation. One of the advantages of this method lies in the fact that the test substance maintains a constant activity in the blood for as long as one hour. The authors describe a variation of Hevesy's method which employs radioactivated whole blood. The blood corpuscles maintain their activity up to sixty minutes, while the activity of plasma falls to one tenth of its original value after five minutes. By the use of this procedure the quantity of blood corpuscles was estimated in 7 cardiac patients both in the stage of decompensation and after compensation had been restored. In decompensated cardiac patients there is an increase not only in the total quantity of blood and plasma but also in the amount of erythrocytes. After compensation is restored, both the plasma and blood corpuscles decrease in quantity. There is a difference in the quantity of blood corpuscles, measured in grams per kilogram of dry body weight (the weight of the body when there is no edema), in decompensated patients and in normal subjects. In decompensated patients the quantity of erythrocytes is, on the average, 36.4 Gm. per kilogram of dry body weight; in normal subjects this value is 31.2 Gm. About the same quantity of erythrocytes is found in compensated cardiac patients as in normal subjects. The authors stress the importance of a knowledge of the form of the dilution curve for the labeled blood corpuscles. Estimation of the circulation time by this method in cardiac patients with dilated hearts but no peripheral edema supports the view that blood is retained in dilated hearts and that this factor greatly influences the estimation of the circulation time.

*Phobia as a Symptom in Hyperthyroidism. B. J. Ficarra and R. A. Nelson.—p. 831.

Phobia as Symptom of Hyperthyroidism.—Ficarra and Nelson studied 115 hyperthyroid patients from a psychologic point of view. The presence of phobias was the presenting symptom. The majority of patients with phobias were women. Eight men were found to have this complaint. In almost all patients the combination of thyroidectomy and intensive psychotherapy resulted in a disappearance of the phobia. This survey argues for an adequate history taking of patients suspected of possessing a phobia or presenting it as a major complaint. To label such persons as neurotic, neurasthenic or psychasthenic may be an injustice. Additional information, an adequate physical examination and laboratory studies should be made to rule out underlying thyroid disease.

Cancer of Cervix.—Kaplan and Rosh review the therapeutic results achieved in patients with cervical cancer treated over a period of twenty-one years at Bellevue Hospital, New York. Of the 916 patients treated by the authors, 179 were alive five years or more and 60 ten years or more after treatment. Eight patients developed recurrence or metastases seven and eight years after treatment. Thirty-four whose condition was classified as hopeless, grade 4, were irradiated because of special request. One of these lived eight years and 8 lived four years. These favorable results in hopeless conditions induced the authors to make greater efforts with patients of this type. Treatment of 221 patients was not completed because the patients were lost sight of. In 36 cases other complicating conditions existed. In none of these did irradiation adversely influence the complicating disease. On the basis of their experience over twenty-one years the authors believe that irradiation is the best method of treating cervical cancer. It is the method of choice in all cases but those of stage 1. Even in stage 4 cases irradiation often prolongs life in comfort. The best form of irradiation is a combination of roentgen rays and radium, with roentgen therapy administered first unless persistent hemorrhage demands immediate cauterization of the bleeding area with radium.

Radical Operation for Cancer of Cervix.—Meigs insists that surgical treatment does not wish to compete with irradiation in cancer of the cervix. Irradiation is at present the method of choice and it has not been proved that the surgical treatment is as good or better. The interest in radical surgery is due to the fact that a few early cases do not respond well to irradiation. In these cases surgery may offer a cure. In the 91 cases in which operation has thus far been done the operative mortality has been zero; that is, in properly selected cases surgical treatment can be done with a mortality equal to that of radiation treatment. Most of the operations were done recently, so that few five year results are available. Six months to over five years have elapsed since the operation and about 11 per cent of the patients have died so far. The one great drawback of surgical treatment, the uterovaginal fistula, has been overcome. Positive lymph nodes, the great stumbling block in radiation treatment, may not be quite so serious in surgical treatment. Patients without positive lymph nodes who are carefully selected should do extremely well with surgical treatment. If a means could be found to establish radioresistance before treatment, the results of irradiation and surgery might be better in cancer of the cervix.

Carcinoma of Thyroid in Children.—Rickles presents the histories of 4 children with carcinoma of the thyroid, who ranged in age between 6 and 11 years and who were observed in the course of only two years at the New Orleans Charity Hospital. The first patient is free from disease three years after undergoing only a simple excision of the adenoma which had been present most of her life. This emphasizes that the only difference between a benign and a malignant adenoma of the thyroid is the finding of the vascular invasion in the microscopic examination. The second and third cases are interesting because they concerned sisters; the tumors were practically identical microscopically, and both girls had evidence of hypothyroidism. All three were treated by surgery alone and none have yet shown evidence of recurrence. Case 4 illustrates the difficulty of making a clinical diagnosis of the diffuse type of cancer. Because of his laryngeal pathologic condition this child was carefully followed since the age of 2, and at no time did physical examination of the thyroid region give a hint of a pathologic disorder; the diagnosis was made only by microscopic examination of a metastatic node. His response to surgery and x-ray treatment was excellent and despite the metastases to the local nodes and parathyroid gland there is no evidence of recurrence at present.

Inguinal Hernia.—Garner says that a study of 2,040 patients in the U. S. Veterans Administration Hospital in Dayton, Ohio, operated on for 2,369 primary and 274 recurrent inguinal hernias indicates a trend toward the use of fascial sutures and fascial grafts in hernia repair operations. A concomitant drop in the recurrence rates of hernia apparently justifies this trend. Hernioplastic procedures are more difficult and more time consuming than are herniorrhaphies, but the incidence of cure is so much higher in the former that the additional time required appears to be well spent. There are no more complications following the use of fascia lata sutures and grafts than are encountered when silk sutures are used. The McArthur fascial suture hernioplasty has been almost entirely eliminated from the armamentarium of the author as a result of studies of recurrence rates. This operation is somewhat less effective than herniorrhaphy with silk sutures and decidedly inferior to the *Gallie fascial suture hernioplasty.* The Wangensteen pedicled fascia graft operation is reserved for patients with large defects in the fascia of the abdominal wall which cannot be adequately closed by procedures requiring less extensive dissection. Cooper's ligament offers a firm anchorage for the transversalis fascia and for the external oblique aponeurosis when exclusion of the femoral canal is necessary or when the inguinal ligament is absent or insufficiently strong to insure satisfactory inguinal reconstruction.

Chemotherapy in Perforated Peptic Ulcer.—According to Hirshfeld and his associates the operative mortality attending acute perforation of peptic ulcer is between 15 and 20 per cent. Approximately 80 per cent of the deaths are due to bacterial infection either intraperitoneal or pulmonary. Since most of the bacteria involved in these infections are susceptible to penicillin or streptomycin, it is believed that early and intensive treatment with penicillin and streptomycin of all patients with perforated peptic ulcer would reduce the mortality rate of this disease. Chemotherapy should be considered as an aid in the treatment and should not be substituted for careful surgical treatment or adequate preoperative and postoperative care.

Streptomycin and Lipotrophic Agents in Miliary Tuberculosis.—Godward reports that a patient with proved miliary tuberculosis recovered completely following treatment with streptomycin and lipotrophic agents. The patient received 0.2 Gm. (200,000 units) of streptomycin intramuscularly every three hours, or 1.6 Gm. daily. In addition, he was given 5 Gm. of lipotrophic agents (3 Gm. of methionine, 2 Gm. of choline chloride) a day. The methionine was given in the form of amigen intravenously in the early phase of therapy and orally after foods were tolerated. The choline was given orally. This treatment was given for six months, during which time he received approximately 295 Gm. of streptomycin and 650 Gm.

of the lipotrophic agents. No toxic reactions were encountered during the course of therapy. The apparent recovery of this patient can most likely be attributed to the effect of streptomycin.

Streptomycin in Resection in Pulmonary Tuberculosis.—Glover and his co-workers suggest that streptomycin may well be effective in exerting its stabilizing influence in the preoperative and postoperative period in patients with pulmonary tuberculosis who are operated on in order to prevent the spread of the tuberculous process or to protect areas newly exposed as the result of trauma and manipulation. They present the histories of 5 patients in whom lobectomy or pneumonectomy was combined with streptomycin therapy. They think that the results in these 5 consecutive cases are sufficiently encouraging to warrant the continued trial of combined surgical and antibiotic treatment. While the series is not sufficient to indicate clearly that any prophylactic or therapeutic effect was realized, it is intended to indicate the possibility of utilizing the suppressive effect of streptomycin during the crucial period before, during and after radical surgery. Should streptomycin be successful in preventing bronchogenic and hematogenous extension of pulmonary tuberculosis during and after operation or should it prevent development of such a complication as tuberculous empyema it will reduce surgical mortality and broaden the indications for radical surgical treatment of pulmonary tuberculosis.

Gastroenterology: Review of Literature from July 1945 to July 1946. W. L. Palmer, J. B. Kirsner, W. E. Ricketts and others.—p. 642.

Cerebral Manifestations of Acute Rheumatic Fever.—Warren and Chornyak point out that, whereas Sydenham's chorea is accepted as a rheumatic equivalent and the cause of a variety of behavior disorders, it is not so well known that acute rheumatic fever may produce severe mental changes of a different character and without the motor phenomena typical of Sydenham's chorea. One case of rheumatic encephalitis is reported in which there were decided mental changes, with apparent recovery. Four other cases are presented in which cerebral involvement due to acute rheumatic fever seemed probable. The patients with cerebral manifestations were observed among 207 patients with rheumatic fever in an army post. Acute cerebral reactions occur during the course of rheumatic fever and may constitute a serious problem in treatment and prognosis. The mental symptoms may occur as the presenting picture and with little or no arthritic manifestations. They may precede the arthritic symptoms or they may follow them. Usually the reaction indicates a diffuse involvement of the brain and there are minimal, if any, localizing signs. One patient showed only a localized lesion. There was complete clearing in several days, with no residual paralysis. Rheumatic encephalitis may present a bizarre picture, with hallucinations, phobias and acute panic-like episodes. Delirium, restlessness and even convulsions may appear. In some cases a masklike facies, mental retardation and sleeplessness may be the only symptoms of cerebral involvement. Hyperpyrexia may be a serious complication.

Quantitative Vibratory Sensation in Diabetes, Anemia and Tabes.—According to Barach, vibratory sensation is induced by placing the vibrating tuning fork on one of the bony prominences of the body, from which the vibratory sense is transmitted along sensory paths leading to the cord and brain. The author and his associates use the 13 inch tuning fork of Symns. They have made numerous observations on the vibratory sensation in cases of diabetes mellitus, pernicious anemia and syphilis of the central nervous system for a period of twenty years. Study of the vibratory sensation as estimated with the tuning fork is a clinical method of diagnostic and prognostic value. Vibratory sensation is largely independent of tactile sensation and depends on the transmission of vibratory sense through muscle, bone and joints to the peripheral nerves, posterior roots and posterior columns of the spinal cord to the brain. A normal curve, based on the number of seconds duration of the vibratory sense as induced by a vibrating tuning fork, has been established. There is a decided loss of vibratory sensation in certain diseases, notably diabetes mellitus, pernicious anemia and tabes dorsalis. Not only is this curve of confirmatory diagnostic value as to the existence of these diseases, but the rise or fall of the curve occurs simultaneously with improvement or aggravation of the disease, thus becoming of prognostic value. Notable deviations below the normal throw additional light on the need for intensive treatment.

Transitory Diabetic Syndrome with Meningococcic Meningitis.—Observations at the South View Isolation Hospital in Milwaukee convinced Fox and his associates that a transient diabetic syndrome exists in a high proportion of patients with meningococcic meningitis. Among 233 such patients they detected 58, a fourth of the total, who had the transitory diabetic syndrome. Unless this high frequency is realized, there is likely to be a high percentage of mistaken diagnoses. In 5 of the 58 patients the detection of sugar and acetone in the urine and treatment of diabetic acidosis impeded the diagnosis of meningococcic meningitis. The delay incurred while the diabetic acidosis alone is treated is extremely significant in the swift advance of the pathologic change to a state of irreversibility. Therefore in all cases of coma extensive examination and diagnostic procedures, such as lumbar puncture, must be instituted as a routine measure.

Labyrinthine Symptoms Subsequent to Fenestration.—Brunner and Cutler studied the spontaneous labyrinthine symptoms which are noticed immediately after the fenestration, also the fistula test. Since fenestration creates a fistula in the bony walls of the labyrinth, the operation offers a chance to study labyrinthine symptoms in man under circumstances which in the past could be produced only by experiments on animals. Studies were made on 12 patients undergoing fenestration. It was found that twenty-four hours after fenestration of the labyrinth there is horizontal and rotatory nystagmus of the third degree to the side of the fenestration, which disappears in three to four days, while after surgical injury of the horizontal semicircular canal there is horizontal and rotatory nystagmus of the third degree to the other side, which persists for two to four weeks. If after fenestration of the labyrinth the nystagmus is directed toward the side of the fenestration and decreases in a few days, it is caused by the opening of the perilymphatic space. If the nystagmus is directed toward the other side, or if it continues for more than one week, an infection of the fenestra is likely to occur. Slow oscillatory movements of the eyes and nystagmus of the head do not indicate an infection of the fenestra. After fenestration of the labyrinth the fistula test should be performed with the Politzer bag and not with the cotton applicator. Atypical findings with the fistula test do not necessarily depend on inflammatory changes in the perilymphatic space.

Effects of Diathermy on Tissues Contiguous to Implanted Metals.—According to Etter and his associates the potential danger of short wave diathermy in patients with metals embedded in their tissues has been a subject of much discussion by physiatrists. The danger allegedly arises from the possibility that the diathermy, even in therapeutic dosage, might either heat the metals to temperature sufficiently high to injure contiguous tissues or distort and concentrate the field immediately surrounding the metal. The importance of the problem has increased considerably since the war. In addition to the enormous number of patients with retained shrapnel and other missile fragments, an increasing number of casualties are being treated by permanent or temporary implantation of metals in tissue. Although diathermy is not commonly administered over the brain, its use in the treatment of sinus infections and cerebral vascular disorders might expose metal skull plates to the short wave field. The authors applied short wave diathermy to the tissues of experimental animals in which tantalum and silver plates, foil and wire and stainless steel plates were embedded. The metals were wrapped around the sciatic nerves or inserted into intramuscular or subcutaneous pouches or fitted into skull defects over the intact dura. There was no significant difference between the temperature on the side containing the metal and that on the control side, irrespective of the diathermy machine used, the method of application of the short wave energy or the nature of the metal used. Microscopic examination of tissues contiguous to the metals disclosed no significant destructive effects from diathermy attributable to the presence of the metal.

Extensive Symmetrical Cerebral Calcification and Chorioretinitis in Identical Twins (Toxoplasmosis?).—Abbott and Camp report observations on twin boys aged 11 years who were brought to the Mayo Clinic because of visual disturbances and of disturbances of movement in the right extremities. The disturbances were more evident in the more severely affected of the two boys, who also had bilaterally symmetrical, extensive, dense calcification in the cerebrum with minor involvement of the cerebellum. Both patients had extensive chorioretinitis, which was more severe unilaterally, associated with retinal angiomatosis. Blood serum from each of the twins neutralized toxoplasma organisms. The pathogenesis and the histopathology of this syndrome, symmetrical cerebral calcification, chorioretinitis with retinal angiomatosis and toxoplasmosis, is unknown. Although a degenerative process occurring in symmetrical anomalies of vascular or heterotopic nervous tissue or both may be the causal factor, it would seem more plausible that the syndrome is due to inflammation, probably consequent to chronic toxoplasmosis.

Complete Removal of Craniopharyngioma with Recovery from Blindness.—Grant was unable to find the report of a case of total removal of a suprasellar cyst or craniopharyngioma. He presents such a case. A boy aged 2 years was apparently well until he fell on his forehead. Failing vision began in four days, and the boy was totally blind in twelve days. At operation, four weeks and two days after the onset of blindness, a large suprasellar cystic tumor was collapsed by aspiration and removed intact. It was necessary to divide the right optic nerve to accomplish this. A narrow stalk connected the base of the tumor with the pituitary fossa. Response of the left pupil to light was present two days after operation and the patient was able to see on the seventh day. He now has useful vision. The history suggested strongly that trauma has been a factor in causing blindness. Cushing observed that the history of preceding trauma was surprisingly common as an apparent factor that stirs suprasellar cysts into activity. The absence of blood pigment in the cyst wall and of red blood cells in the cyst fluid would be against the contention that an intracystic hemorrhage had occurred at the time of the blow on the head. When the patient fell on his right forehead one would expect that the tumor would be thrust forward temporarily at the moment of the impact. This could hardly damage the optic nerves without causing visual impairment at once. But it could tear arachnoidal or other bands of tissue that were constricting the tumor. This would allow the lesion to expand gradually after the injury and would seem to fit the train of events in the present case.

Rh and Hr Factors.—Hunt and Lucia say that the presence of any Rh antibodies, either agglutinating or blocking, indicates sensitization of the host with Rh positive erythrocytes either from a blood transfusion or from a current or previous pregnancy. If antibodies are found during the first few months of pregnancy and increase as the pregnancy progresses they may indicate (*a*) a rise of antibodies initially formed in the past and bearing no relation to the Rh characteristic of the fetus in utero; in such an instance the infant would be unaffected; (*b*) an Rh positive fetus producing specific sensitization of the mother; in such an instance the infant might be afflicted with hemolytic disease. If antibodies occur only within the last few weeks of pregnancy they may indicate initial sensitization in a mother not previously exposed to the Rh factor; in such an instance the infant might show mild symptoms of hemolytic disease of the newborn or be clinically normal. About 10 per cent of the mothers of infants with hemolytic disease have no evidence of Rh sensitization. In these cases the disease is due to the A-B-O and Hr sensitization and other mechanisms. On the other hand, a clinically normal Rh positive child may be born to an Rh negative mother who shows abundant evidence of current Rh sensitization.

Thyrotoxicosis Complicated by Severe Iodism: Preparation for Surgery with Propyl-Thiouracil. E. A. Newman and P. H. Ross.—p. 212.

Excretion of 17-Ketosteroids in Ankylosing Spondylarthritis.—Davison and his associates found that the urinary excretion of 17-ketosteroids in 13 male patients with ankylosing spondylarthritis (Marie-Strümpell type) averaged 27.3 mg. in twenty-four hours as compared with an average of 14 mg. for normal males. In 11 females with rheumatoid arthritis the average urinary excretion of 17-ketosteroids was 12.8 mg. as compared with an average value of 10 mg. for normal females. Thus there seems to be a trend to greater excretion of 17-ketosteroids in ankylosing spondylarthritis, a disease largely confined to males, whereas, in typical polyarticular rheumatoid arthritis in females this tendency is not demonstrated.

Insulin Regulation in 126 Diabetic Children.—Mosenthal and Rosen observed the insulin regulation of 126 children at a summer camp for diabetic children during July and August 1946. Three types of insulin were used: regular insulin, protamine zinc insulin and globin insulin with zinc. Only protamine zinc insulin and globin insulin with zinc were satisfactory when given as the sole insulin, while regular insulin was a distinct failure in many instances. Protamine zinc insulin and regular insulin by separate injections had to be replaced by other forms of insulin in many cases. Besides the disadvantage of a double injection, this form of insulin therapy proved less satisfactory than the insulin mixtures made in one syringe. Mixtures of protamine zinc insulin and regular insulin prepared in one syringe proved effective. Where insulin changes were believed advisable, the routine switch was made to a mixture of 1 part of protamine zinc insulin to 2 parts of regular insulin advocated by Colwell as the most generally applicable insulin. The authors believe that globin insulin with zinc would have yielded equally good results. Although the idea that protamine zinc insulin should not exceed the amount of regular insulin in one syringe mixtures is prevalent, it was shown that protamine zinc insulin was often greater in amount than regular insulin for optimal results.

Male Hypogonadism Treated by Sublingual Methyltestosterone. R. S. Finkler.—p. 293.

Radio Iodine as a Tool in the Study of Thyroid Physiology.—Rawson and McArthur point out that the study of thyroid physiology with radioactive isotopes of iodine was started in 1937. They review the collection of iodine by the thyroid and the effect of the thyrotropic hormone, studies on the chemical transformation of administered radioactive iodine, the effect of certain thyroid inhibitors on the metabolism of iodine, the use of radio iodine in the study of human thyroid disease, the treatment of hyperthyroidism with radioactive iodine and the collection of radioactive iodine by thyroid tumors. They maintain that radioactive iodine in thyroid cancer will be possible only in exceptional cases unless means can be found to increase the avidity of thyroid tumors for iodine. It has proved a valuable tool for the study of thyroid physiology. Certain principles of thyroid function which were demonstrated with the classic biochemical technic have been reinforced and amplified. Progress toward the solution of the steps involved in the synthesis of the natural thyroid hormone has been facilitated. The mode of action of certain goitrogenic thyroid-inhibiting agents has been clarified. Knowledge of iodine metabolism in hyperthyroidism has been advanced and some correlation has been demonstrated between the structure and the function of benign and malignant tumors of the thyroid. In adequate dosage radioactive iodine has proved to be a therapeutic agent of value in certain selected cases of hyperthyroidism and in exceptional instances of thyroid cancer.

Electroshock in Psychiatric Illness Complicated by Pulmonary Tuberculosis.—Will reports the experience of a man aged 21 in whom an apparently latent pulmonary lesion (considered to be tuberculosis but not confirmed by the finding of bacilli) became activated shortly after the completion of a series of eight electroshock treatments. It is possible that the convulsive therapy played an important role in this activation. The spread of the tuberculous process may be encouraged by the development of scattered petechial pulmonary hemorrhages resulting from the violence of the seizure. The use of curare to control the convulsive movements and thus reduce the incidence of such hemorrhages might be helpful in treating cases complicated by pulmonary tuberculosis. Electroshock in patients with latent or active pulmonary tuberculosis may be attended with some risk, although pulmonary tuberculosis is not a definite contraindication to such therapy. Each case should be evaluated individually.

Is Cobalt a Dietary Essential for the Rabbit? J. F. Thompson and G. H. Ellis.—p. 121.

Supplemental Relationship Between Pork and Egg Proteins.—According to Hoagland and his co-workers the supplemental relationship of the protein in one food product to that in another is of great practical importance in human nutrition. In 1945 they reported that pork protein had a decided supplemental relationship to bread protein, and the question then arose as to the possibility of a similar relationship between pork protein and egg protein. The authors determined the supplemental relationship between the protein in pork and that in eggs by experiments with young male albino rats. The protein in both fresh and cured hams contained insufficient cystine and methionine for optimum growth in rats when the diets contained 10 per cent of protein; but when pork protein was supplemented with these amino acids, the growth promoting value was equal to that of protein in eggs. There was found to be a moderate supplemental relationship between the protein in ham and that in eggs. Mixtures of equal parts of pork and egg protein had approximately the same growth promoting value as egg protein alone.

Growth and Longevity with Omnivorous and Vegetarian Diets.—Comparative studies of the effects of omnivorous and purely vegetarian diets on the growth and longevity of rats seemed of interest to Carlson and Hoelzel in view of the fact that the increasing population of the world tends to compel the use of a larger proportion of foods of vegetable origin in the human diet and the view is widely held that a vegetarian diet promotes health and longevity. The authors describe the growth of rats fed omnivorous and vegetarian diets during two longevity studies and during additional short term studies. Two of 9 male Wistar rats attained weights of 870 and 890 Gm. respectively on an omnivorous diet including about 35 per cent protein (chiefly meat protein) and 28 per cent fat. Rats fed purely vegetarian diets were stunted in growth. Rats fed an omnivorous diet lived significantly longer than rats fed a vegetarian diet. The life span was more uniformly prolonged by the intermittent fasting of rats fed an omnivorous diet than in rats fed a vegetarian diet.

Report on 2 Unusual Cases Involving Foreign Bodies. J. I. Kemler.—p. 419.

Fenestration Operation:—Lindsay points out that the estimated percentage of successes and failures of the Lempert nov-ovalis fenestration operation has varied, but the basic fact has been established that satisfactory results may be achieved in a sufficiently high percentage to warrant the operation in suitable cases. A statement of the percentage of good results falls short of giving a complete picture. There are varying degrees of success, and although the hearing may be improved above the 30 decibel average threshold for speech frequencies and be generally satisfactory to the patient, many of these operations must be considered as only partly successful in that the maximum postoperative gain may not have been maintained or may never have been reached. The author concludes that mplete closure of the fenestra after the Lempert nov-ovalis eration has become an infrequent complication. A decrease the hearing improvement for low frequency in the third to sixth month is common and is evident in many cases which may still be classed as successful results. Hearing for the 2,048 and 4,096 region is most consistently maintained after operation. This region is most important for speech perception. A comparison between preoperative bone conduction thresholds and the maximum postoperative hearing gain has shown a close correlation. The possibility for improvement in speech perception appears to be most accurately indicated by the preoperative bone conduction threshold values at 2,048 and 1,024 cycles.

Etiology of Scleroderma.—Wuerthele-Caspe and her associates had reason to suspect a bacterial origin of scleroderma. On the supposition that the organism is a mycobacterium as in leprosy and tuberculosis, it was reasoned that it should be found in nasal ulcers, subcutaneous tissue and sputum when there is pulmonary involvement. Material was prepared from the sputum of a proved case of scleroderma. When the slides were stained by the Ziehl-Neelson method, numerous short, thick, acid-fast rods were seen. Subsequently the differential triple stain technic of Alexander-Jackson was employed and a team of investigators was formed to identify the organism. Five case histories are presented to demonstrate the results of these studies. The organism has been found in the sputum, in the blood and in nasal and subcutaneous tissue smears and has been grown in pure culture from the blood. All patients treated with promin (which destroys or inhibits mycobacteria) have shown responsive changes. The organism has been tentatively named Sclerobacillus Wuerthele-Caspe and may be a new member of the family of mycobacteria. Further studies are in progress.

Electrolysis. H. M. Robinson.—p. 618.

Complications Following Radiotherapy of Carcinoma of Cervix Uteri.—According to Thomas, irradiation is regarded as the method of choice in the treatment of cervical carcinoma. Complications of radiation therapy still occur in spite of the advances in the methods of administration and the safeguards now being employed. Sufficient treatment to destroy or arrest the carcinoma may cause certain and unavoidable damage to contiguous structures. The vaginal mucosa routinely develops an epithelitis manifested by reddening, edema and desquamation. Soothing deodorant douches are helpful. Adhesive vaginitis with occlusion of the canal should be prevented by manual and prosthetic dilations. Patients frequently show evidence of a mild bladder mucosal irritation during treatment or shortly thereafter. Bladder sedatives give much relief. Serious bladder complications do not appear until a year or more after irradiation unless there has been malposition of the radium. The incidence of rectal mucosal irritation is extremely high. Rarely does a patient go through the cycle of therapy without manifesting some proctitis. Paregoric, warm saline enemas and rectal instillations of a bland oil are helpful in alleviating the symptoms. The natural course is toward a spontaneous cure in most patients. Follow-up care is often neglected. Frequent follow-up examinations are necessary for the early recognition and treatment of the complications.

Abdominoperineal Proctosigmoidectomy for Rectal Cancer Complicating Pregnancy.—Bacon and Rowe recently cared for 4 patients in whom carcinoma of the rectum complicated pregnancy. Abdominoperineal proctosigmoidectomy without colostomy and with preservation of the sphincter muscle was performed in all with uneventful recovery. The histories of these patients are presented. Review of the literature revealed 70 cases in which cancer of the lower bowel complicated pregnancy but in many of which the tumor was not diagnosed. The symptoms in these cases are relatively the same as in any other cancer of the lower bowel, but they may be overshadowed by those of the pregnancy. Digital examination, proctosigmoidoscopy and opaque enema study are not contraindicated during pregnancy. Pertinent to the management of this complication the following procedures are recommended: (*a*) in early pregnancy (three months or less), abdominoperineal proctosigmoidectomy without colostomy and with preservation of the sphincter musculature, or, as a second choice, a Miles abdominoperineal extirpation, especially when the lesion is less than 6 cm. from the anal margin, and with relative disregard to the pregnancy; (*b*) in the second trimester where the fetus is not viable and the size of the uterus would necessarily interfere with removal of the growth, Porro section and resection simultaneously if the condition of the patient warrants such a procedure; (*c*) in the last trimester of pregnancy, cesarean section and hysterectomy followed by removal of the cancerous bowel two to four weeks later.

Parenteral Fluids and Body Fluid Equilibrium.—According to Moyer and his associates the indiscriminate use of parenteral and oral fluids may produce serious illness. The intravenous infusion of 0.9 per cent sodium chloride in water or in 5 per cent dextrose solution may be followed by a relative deficit of water, the retention of the salt solution in the body or the development of a deficiency of potassium. These changes in the composition or the volume of the body fluids may occur singly and in various combinations. Whether or not a relative deficit of water occurs during the administration of a 0.9 per cent sodium chloride solution, when it is the only parenteral fluid given, depends primarily on the patient's ability to excrete the salt injected in a sufficiently higher concentration in the urine than its concentration in the infusate so that a volume of water equivalent to that lost insensibly through the skin and the respiratory tract may be abstracted from the administered solution. The failure to abstract enough water from isotonic salt solutions may also be due to the failure to give enough of it or the failure to excrete enough urine. The development of a relative water deficit can be prevented by the use of 0.6 per cent saline solutions whenever large combined salt and water deficits need correction. The use of a hypotonic salt solution (0.6 per cent or less) will not prevent the retention of salt if it be given when it is not needed. The injudicious employment of 5 per cent dextrose solution intravenously or water orally may lead to serious illness whenever amounts are prescribed that are greater than the sum of the insensible loss of water and the maximum excretory capacity of the kidney for water. The latter may be severely depressed during illnesses and after surgical procedures. Illustrative case summaries are presented.

Penicillin in Bacterial Endocarditis.—Jones and his collaborators say that by 1945 it was realized that to be successful penicillin has to be administered in large doses for long periods. Up to a million units has been given daily and the treatment has been continued for up to five to eight weeks. At the Manchester Center, 40 cases have so far been treated, but 7, in which less than six months have elapsed since treatment, are excluded from this review. Fifteen of the 33 unselected patients died. The degree of recovery is assessed in 18 successful cases. Although most patients resume their old occupations, increased residual cardiac damage is the rule and a small proportion may develop stenotic valvular lesions. Relapses following inadequate therapy, if promptly detected and adequately treated, do not appear to prejudice the ultimate outcome. The process of healing was studied microscopically in 12 cases and it was found that healing is not advanced until three months after clinical control of the infection. The authors discuss the causes of death in 15 cases and describe the postmortem aspects of 13 cases. They stress the importance of heart failure in causing death and say that cardiac damage caused by the infection is the chief cause of failure. Microscopic study of renal lesions in 11 cases showed that diffuse, not focal, glomerular lesions predominate. It is assumed that if similar lesions occur in patients who recover they may later cause renal insufficiency. Seven cases associated with pregnancy are discussed; 5 of the mothers and 6 of the children survived. In 1 case with an infected patent ductus arteriosus the ductus was ligated four months after successful penicillin treatment. The authors gained the impression that the duration of the infection before treatment is of greatest importance for the prognosis.

Splints for Fractured Noses. M. C. Oldfield.—p. 886.

Social and Occupational Factors in Skin Cancer.—Ryle and Russell, analyzing data obtained from annual reports of the registrar general for the United Kingdom and Eire, state that the annual number of deaths from cancer of the skin, excluding that of the penis and scrotum, is approximately 1,000 per annum in England and Wales, and the mortality in males is about 70 per cent in excess of that in females. The face is the principal site involved. The ear is next in frequency. The mortality has a definite gradient with social grouping for the wives of workers, but for the males it would seem to have both a social and an occupational relationship, and the latter is seemingly the more important. The anatomic character of some of the sites affected suggest, on the one hand, that atmospheric soot or other grime (as in the case of scrotal cancer) may need to be considered as an etiologic factor. On the other hand, ultraviolet radiation from the sun may be responsible for skin cancers in exposed sites. Heat, or heat plus grime, may be operative in such occupations as that of furnacemen, if the face and hands of these workers should be shown to be frequently involved.

Penicillin in the Treatment of Diphtheria.—Long considers the rapid elimination of pathogens with the prevention of further toxin formation as the aim of penicillin treatment of diphtheria. Reports in the literature, particularly those of Karelitz, induced him to employ much larger doses than had been employed before. Of 3 patients whose treatment was reported in detail, 2 were given 1 million units daily for three days and the third was given half a million units. This patient, who was less toxic than the other 2, recovered like the first 2, but her convalescence was complicated. Three further cases have been treated. All were mild, a million units of penicillin a day for three days was administered, and in none was it possible to demonstrate diphtheria bacilli after the first day's treatment. The author concludes that at least 1 million units a day would appear to be desirable in severe cases. The value of penicillin is particularly striking in the presence of secondary infection. The importance of early adequate antitoxin administration is emphasized.

Bilateral Pneumothorax After Partial Thyroidectomy. B. R. Billimoria.—p. 871.

Infection of Wounds with Gram-Negative Organisms.—The observations of Florey and his associates were made on 53 battle casualties with 63 lacerated wounds mainly involving compound comminuted fractures of the tibia and on 10 further superficial wounds caused by pressure sores and plastic operations. Since all the patients had received prophylactic injections of penicillin for various periods after wounding and continued to receive prophylactic local applications or intramuscular injections throughout their treatment, the gram-positive organisms commonly considered responsible for major sepsis were of minor significance. Clostridia were not a problem for more than three weeks in most wounds. It had been hoped to compare the state and progress of wounds containing gram-negative bacteria with those of wounds in which these organisms were not present; but 51 of the 56 which could not be closed by secondary suture harbored one or more species of gram-negative bacteria from the second week after wounding onward. It was therefore impossible to assess effects against a comparable number of controls. Lysis of surrounding clot, persistence of discharge and consequent interference with the processes of bony and soft tissue repair seem to be the main effect of gram-negative infection. Bacteriologic and clinical effects were observed of the daily local application of different agents in reducing the infection. Streptomycin was most effective in removing Escherichia coli, Pseudomonas pyocyanea and Proteus both rapidly and permanently in a few wounds. Sulfathiazole was effective in eliminating Escherichia coli and Proteus to a lesser degree. Sulfamezathine had a similar effect on Escherichia coli and Pseudomonas pyocyanea. The presence of Staphylococcus aureus in the wound was almost as effective as the two sulfonamides in reducing the gram-negative population. Neither operation nor enclosure in plaster of paris had any pronounced influence on the infection. Clinical application of these findings showed that deliberate use of the sulfonamides, with penicillin when necessary, or the use of streptomycin, could sterilize persistent sinuses so that they healed rapidly.

Intradermal Reaction in Trichomonas Infection.—Since it is not difficult to prepare bacteria free cultures of Trichomonas vaginalis by exploiting the bacteriostatic action of sulfonamides and penicillin, Adler and Sadowsky prepared antigens for such cultures and investigated whether vaginal infection with Trichomonas vaginalis produces any detectable immunologic reaction in the host. They found that in 35 of 43 women with a vaginal infection with Trichomonas vaginalis a skin test twenty-four hours after intradermal inoculation with 0.1 cc. of an aqueous extract of 1,000,000 (and in some cases of 2,000,000) flagellates per cubic centimeter gave a positive reaction. In 45 of 58 women negative on microscopic examination there was no reaction. Antigen of Trichomonas vaginalis is absorbed through the wall of the vagina.

Refrigeration Anesthesia; Report of a Case. J. G. Toakley.—p. 729.

Puerperal Tetanus.—According to Tonge, few cases of puerperal tetanus have been reported, and most of these have not been confirmed bacteriologically. Observations on 3 patients are reported in this paper: 1. A woman aged 27 developed pulmonary embolism on the seventh day and on the fourteenth day symptoms of tetanus from which she died. Clostridium tetani was recovered post mortem from the infarct in the lung and from the cervix uteri. The author is convinced that it is difficult to decide whether puerperal tetanus arises from the use of unsterile catgut, from vulval pads or by autoinfection from the patient's bowel. 2. Tetanus developed on the ninth day after an instrumental delivery and manual removal of the placenta. The tetanus proved fatal. 3. Tetanus developed after an induced abortion. Symptoms developed on the eighth day, and death followed on the thirteenth day after abortion.

Schistosomiasis: Review of Work in Southern Rhodesia in 1946. W. Alves and D. M. Blair.—p. 352.
Sporadic Cretinism and Ichthyosis in Same Family. J. Helman.—p. 358.

Criticism of Treatment of Varicose Veins.—Garber believes that sclerosing injections have nothing to recommend them, for not only do they fail to cure but they expose the patient to loss of life or limb, prolonged morbidity or expense. Similar penalties beset operation coupled with the use of sclerosants. In the multiple resection operation the writer envisages a surgical procedure not difficult of accomplishment by the trained surgeon. It is free of hazards associated with sclerosants, and it extends the promise of permanent cure in young or old, without the added burden of pain or prolonged disablement. The author believes that, when the great saphenous is subdivided into segments ¾ to 1 inch long, tied at both ends with fine silk, the influence of all perforators, actual or potential (channels concatenating the great and small saphenous to the deep veins), becomes nullified as the T shaped fragments rapidly thrombose and cicatrize. Not only is the operation effective in the thigh, but it is preeminently suited for obliteration of the numerous perforators in the calf. The attention bestowed on the great and small saphenous veins should likewise be devoted to isolated varicose perforators (gluteal, calf and popliteal) and to the vessels draining the skin and passing directly to the femoral vein, but avoiding the great saphenous. Certain authors utilize venous competency tests to correlate operative measures with the degree of varicose transformation in veins. Garber disapproves of this policy. He thinks that, since varicosity is progressive and since there is a proved remedy, it should be employed in as many cases as possible.

*Importance of Aseptic Technic and Fallaciousness of Chemical Bacteriostatics in Blood Banking and Plasma Preserving. B. Swedberg, G. Widström and K. Alin.—p. 480.

Liver Biopsy in Thyrotoxicosis.—Piper and Poulsen studied the functional capacity of the liver in 30 patients with thyrotoxicosis. Liver biopsy by means of Iversen and Roholm's method was performed on 15 of these patients. Little or no functional impairment was demonstrated by the functional tests. Biopsy revealed only slight and atypical changes; the glycogen content was reduced in 7 patients, there was mild steatosis in 3, delicate dark streaks of cells as in chronic irritation were presented by 5, slight round cell infiltration was observed in 2 and hyalinized connective tissue was seen in 1 patient. It is concluded that even in pronounced cases of thyrotoxicosis the functional capacity of the liver is affected to only a slight extent. The presence of anatomic changes in the liver of these patients cannot be demonstrated by aspiration biopsy. The prognosis of surgical intervention in thyrotoxicosis is not aided by liver biopsy. In the absence of definite signs of damage to the liver there is no particular reason to postpone surgical treatment under general anesthesia.

Endocrine and Mental Disorders in Poliomyelitis.—Luft and Müller examined 66 persons, 54 of whom had acute poliomyelitis during the period of 1944 to 1945 and 12 during the period of 1934 to 1936; endocrine disorders were observed in 20 of these patients, all of whom were women. The endocrine disorders varied to a large extent; there were menstrual disorders in 8 patients, changes of body weight in 11, disturbances of sexual development and that of the body in 3, increased thirst in 3. Decreased dextrose tolerance was demonstrated in 14 patients on whom dextrose tolerance tests were performed. Hypertrichosis was present in 24 patients. It was most common in patients with pronounced paresis of the extremities. In several of these cases the hypertrichosis was probably a manifestation of a trophic disorder following injury of the peripheral neuron. Mental disorders were observed in 36 of the 66 patients. Those who had poliomyelitis as adults showed mental disorders of the organic neurasthenic type. In 4 of the 7 patients who had the disease during childhood a change of personality was noticed. The frequency of mental disorders was equal in childhood and in adults. Physical invalidity was of little importance for the development of mental disorders. There was no correlation between clinical signs of encephalitis during the acute stage of poliomyelitis and endocrine or mental disorders in the afterstage. Endocrine and mental disorders appeared independently of each other. The pathologic-anatomic basis of these endocrine and mental disorders is obscure; they could be considered as manifestations of inflammatory changes in the hypothalamus.

Aseptic Technic in Blood Banking and Plasma Preserving.—Widström's method for the production of plasma for military use in Sweden from 1943 to 1945 is an open method with considerable possibilities of bacterial infection. Experiments carried out by Swedberg and his co-workers verified Novak's experience that sulfathiazole has a distinct bacteriostatic effect against both staphylococci and Escherichia coli. By the addition of 100 mg. of sulfathiazole per hundred cubic centimeters and rapid cooling of the blood and plasma preparation within five days it was believed that bacterial growth in the blood might be prevented. The plasma was stored, when ready, at —15 to —25 C. and sterilized by filtration immediately before drying. The clinical results with this plasma were good. Most of the plasma was dried immediately, but some was stored in the liquid state to afford experience with this method of storage. Bacterial and fungoid growth was demonstrated on bacteriologic examination one to one and a half years later. Complete resistance of this growth to sulfathiazole (500 mg. per hundred cubic centimeters) as well as to merthiolate concentrations demonstrated again the importance of aseptic methods of production from the collection of the blood to the dispensation of the finished plasma. No bacteriostatic addition can take the place of aseptic technic.

Urethane in Treatment of Chronic Leukemias.—Experimental studies had demonstrated that urethane inhibits tumor growth in animals. Haddow and his collaborators found that results obtained with urethane compared favorably with those obtained with roentgen therapy. Schulze treated chronic leukemias of the myeloid and lymphatic types with urethane. He describes observations on 5 patients with chronic myeloid leukemia and 2 with chronic lymphatic leukemia subjected to urethane treatment. Urethane, which is an ethyl carbamate, was first given by mouth, the individual dose amounting to 1 Gm. and the daily dose varying between 3 and 5 Gm. The patients usually tolerated the medicament in this form for about eight days, when gastric disturbances often set in. Medication was then continued by clyster. The number of leukocytes could be reduced to practically normal values. The differential white blood picture was practically normalized in the myeloid forms of leukemia, in which the therapeutic response was best. The immature leukocytes disappeared almost completely from the peripheral blood. Existing splenic tumors decreased in size and, when anemia accompanied the leukemia, hemoglobin and erythrocytes usually increased. The action of urethane may be due to its toxic effect on mitosis.

Paradoxical Condition of Vasoconstrictors of Face.—Leriche reports the occurrence of a paradoxical syndrome of the vasoconstrictors of the face in a man aged 32. The patient presented a sudden redness of the entire face associated with a sensation of heat, mild vertigo and headache any time during winter and fall when he went outdoors, leaving the warm atmosphere of his room and exposing himself to the cold. The cold produced an active vasodilatation, more pronounced than that which follows anesthesia of the stellate ganglion or excision of the superior cervical sympathetic ganglion. The syndrome occurred in the absence of any cause; active hyperemia was produced by factors which normally cause vasoconstriction. It is apparently an instance of an inversion of the reaction to cold. Induced anesthesia of the stellate ganglion was followed immediately by an oculopupillary syndrome and then by vasoconstriction of the conjunctival vessels and of those of the face. The vasomotor reaction therefore was inverted; there was no therapeutic result.

Lobectomy in Treatment of Residual Cavities.—Brunner says that following chronic pulmonary abscesses there often remain more or less extensive cavities with bronchial fistulas which do not close completely in spite of adequate thoracoplasty. The term "latticed lung" is often applied to these cavities because adhesions and niches create the impression of lattice work. After pointing out that the operation of Garrè-Lebsche is difficult and involves the danger of air embolism and that muscle plastic according to Nissen also involves certain difficulties, he suggests that lobectomy is advisable whenever the major portion of a pulmonary lobe is occupied by a residual cavity or if, in addition to a cavity, bronchiectasis causes considerable production of pus. He demonstrates on the basis of 3 case reports that lobectomy will produce cure without a persisting fistula even if there was a large cavity and continued pus secretion.

Traumatic Tuberculosis.—The 2 cases reported by Löffler represent classic examples of decisive change in the course of existing tuberculous process by intercurrent traumas. 1. A man aged 53 who had been well had a fall in which his chest violently struck the ground in the region of an old calcified pulmonary process. Eight days after the fall he had a hemoptysis and a rise in temperature. Twenty-four days after the accident irregular fever developed, and on the sixtieth day a roentgenogram demonstrated miliary tuberculosis, whereas twelve days after the accident a roentgenogram had been negative as regards miliary tuberculosis. Eighty-six days after the fall the patient died. Necropsy revealed a hematogenic miliary dissemination and a bronchogenic dissemination by aspiration. 2. A woman aged 32 sustained a trauma of the abdomen with muscular contusion and hemorrhage of the bladder. At the age of 28 she had had open tuberculosis on the right side, for which sanatorium treatment, phrenic exeresis and pneumothorax had been given. The tuberculosis had become arrested. Several months after the accident there appeared signs of renewed activity of the tuberculous process, with increase in temperature, night sweats, reappearance of tubercle bacilli in the sputum and appearance of an area of infiltration. The thrust against the abdomen was transmitted to the thorax the more readily because the patient had undergone a phrenic exeresis.

Book Notices

Nutritional and Vitamin Therapy in General Practice. By Edgar S. Gordon, M.D., Ph.D., Associate Professor of Medicine, University of Wisconsin, Madison. Third edition. Cloth. Price, $5. Pp. 410, with 47 illustrations. Year Book Publishers, Inc., 304 S. Dearborn St., Chicago 4, 1947.

The third edition of this practical physician's guide maintains the same high quality as was found in earlier editions. It is a condensed outline and evaluation of the present status of information. At times the text appears to be ultraconservative. On the other hand, one is rather surprised at the inclusion of highly technical material which can be of little interest to the clinician. It might be worth while to ascertain how many practitioners are interested in the biophotometer or the structural formulas of various compounds. Diagnosis of deficiencies and practical methods of treatment constitute the greatest contribution of the work. The illustrations supporting this part of the work are, accordingly, most valuable. The discussion of protein, fat and carbohydrate appears to be a trifle too sketchy, although there are certainly no misstatements. The chapters on weight control and on dental nutrition are especially sane. Reading the chapter on the economic side of clinical nutrition, one has an impression that the author is floundering a bit. The table on page 374 is especially good, however. An appendix carries a good list of commercial preparations. Also there is a brief statement of laboratory methods of vitamin assay which contains about all that a practitioner is likely to need on this subject. The tables on nutritive values of selected foods would be much more valuable if stated in terms of average servings rather than in 100 Gm. portions. Most clinicians find it sufficiently exact to prescribe diets in terms of everyday experience.

Oral Surgery. By Sterling V. Mead, D.D.S., M.S., B.S. Third edition. Cloth. Price, $15. Pp. 1,150, with 821 illustrations. C. V. Mosby Co., 3207 Washington Blvd., St. Louis 3, 1946.

Since its first edition in 1934, this has probably been the most complete and comprehensive textbook for the dental student as well as the practicing dentist. It thoroughly covers all phases of oral surgery and can be successfully used as a reference work by the specialist. The third edition brings the book up to date by presenting knowledge obtained since publication of his second edition and also makes certain corrections in the text. A few of the notable additions are the many improvements in oral surgery which resulted from the war, the chapter on chemotherapy, which discusses at length the sulfonamide drugs as well as penicillin, the chapter on nutrition, which places a new value and importance on the relationship of diet and oral health, and improved methods of surgery and prostheses in orofacial deformities. The subject matter is presented clearly. It is not merely the opinions of the author but is backed up by actual clinical experiences of the author or some other authority. The book is well organized and contains an unusual number of excellent illustrations and diagrams. The various technical procedures are particularly well illustrated. A book of this type and caliber continually proves its worth in the field of dentistry.

The Acoustic Impedance Measured on Normal and Pathological Ears: Orientating Studies on the Applicability of Impedance Measurement in Otological Diagnosis. By Otto Metz. Denne Afhandling er af det lægevidenskabelige Fakultet antaget til offentligt at forsvares for den medicinske Doktorgrad, København. Paper. Price, 10 Danish kroner. Pp. 254, with 30 illustrations. Einar Munksgaard, Nørregade 6, Copenhagen K, 1946.

This is a comprehensive discussion on methods and means to find an empirical correlation between the acoustic impedance of the ear as measured at the tympanum and conductive deafness, as described in otologic terminology. The hope no doubt was that ultimately such a measurement could be perfected as a useful routine diagnostic test. The conclusion seems to be that it is still in a hopeful experimental stage.

A measurement of acoustic impedance may be regarded as an extension, quantitative and qualitative, of the older tests of "mobility" of the tympanum and its surrounding appendages. Being purely an external test, it can hardly be expected by itself alone to discriminate clearly between different kinds of conductive lesions in the complex measurement beyond the drum unless it is found later that such lesions invariably follow a simple pattern. The solution of the problem of the dynamics of normal conduction through the middle ear would seem to be a substantial help if not a necessary prerequisite to such a development.

The subjects covered in this volume are pertinent fundamental principles of acoustics, acoustic impedance apparatus and measurement, previous work on ear impedance, test room technics, sources of error, normal ears and abnormal ears, followed by several sections devoted to the study of the relation of these to other tests and diagnoses.

The work has been done with great care and attention to detail and represents a substantial contribution to a much neglected phase of scientific otologic literature.

Traité de neuro-endocrinologie: Le système neuro-endocrinien, le complexe hypothalamo-hypophysaire, la neuro-ergonologie et son évolution récente. Par Gustave Roussy et Michel Mosinger. Paper. Price, 2,200 francs. Pp. 1,106, with 261 illustrations, Masson & Cie, 120 Boulevard Saint-Germain, Paris 6e, 1946.

The authors have written an important, timely and fully authoritative treatise on the relationships between the nervous system and the endocrine glands. The book is divided into five parts: 1. An excellent description of the neurovegetative system, with special reference to its relation to endocrine functions. 2. Several chapters on the nervous system in general. 3. A section on the physiologic and related histologic descriptions of neuroglandular correlations. 4. Pathologic processes and variations encountered in the neuroendocrine system. 5. A description of catalyzers, hormones and enzymes and their functions in the body economy. The illustrations are partly diagrammatic and partly photomicrographs. Most of them are quite good.

The authors put emphasis on the hypothalamus and its outgoing fibers in explaining endocrine syndromes. This is most praiseworthy, since such considerations help greatly in explaining the genesis and expected degree of success in the treatment of glandular disturbances. While it may be difficult for the clinician to read the book in its entirety, it should prove most valuable for frequent and constant reference. The arrangement and the many integrated subdivisions with an abundance of subtitles makes for ease of use for all those who can read French. The style is lucid, readable and not too involved. The reader is also helped by an extensive bibliography. The book shows the wealth of digested information the authors seem to possess.

Diagnostic hormonal et traitements hormonaux en gynécologie. Par Claude Béclère. Préface du Professeur H. Simonnet. Paper. Price, 525 francs. Pp. 371. Masson & Cie, 120 Boulevard Saint-Germain, Paris 6e 1946.

Béclère has written a well arranged treatise on the relationship of hormonal influences to gynecologic disorders. He has presented it sufficiently clear and simple to be useful not only to the gynecologist but, equally and perhaps more so, to the practitioner.

The book has three main divisions: (1) the normal physiologic considerations as they exist during the principal periods in the life of the female, (2) an exhaustive description of the useful hormones used in practice, with indications and dosage of each, and (3) diagnosis and treatment of hormonal disturbances and diseases caused by them. A section is also included describing laboratory methods for measuring hormone excretions.

Throughout the text the author shows his thorough knowledge of the subject and his apparent experience in teaching. It is refreshing to note that the use of testosterone in the female receives the adequate status it deserves, a subject from which a number of authorities have shied away because they felt that "male" hormones should not be used in the female. Caution is advised, however, throughout in its use. A unique chapter deals with the hormonal causation and treatment of uterine fibroids. Although the author leans toward the use of testosterone rather than progesterone, American authors lean more toward the latter. Otherwise the book follows fairly closely the books seen in American literature. The work may well be recommended.

Aural Atlas. Edited by Samuel J. Kopetzky, M.D., F.A.C.S., Acting Otolaryngologist, New York Polyclinic Medical School & Hospital, New York, Ralph Almour, M.D., F.A.C.S., Professor of Otolaryngology, New York Polyclinic Medical School & Hospital, Julius Bell, M.D., F.A.C.S., Instructor in Otolaryngology, New York Polyclinic Medical School & Hospital, and Murray B. Gordon, M.D., F.A.C.P., Professor of Clinical Pediatrics, Long Island College of Medicine, Brooklyn. Fabrikold. No pagination, with 4 plates by Alfred Feinberg and 45 illustrations by Eve Madsen. Auralgan Research Division, New York, 1946.

This small atlas contains forty-nine plates depicting the various structural and pathologic conditions that are so often seen clinically. The paper is of excellent quality. The illustrations and titles are crystal clear. This atlas should interest every physician, though the pediatricians and otologists will find it of greater value than those in other specialties. The general practitioner ought to derive much information from these pages since they offer a visual review of the drum membrane in different otitic infections. The atlas may also serve as an aid in teaching, and perhaps occasionally the pediatrician or otologist might show the approximate illustration to an intelligent patient, thus obviating the necessity of wasting his valuable time to explain a certain otitic condition to one not familiar with otology.

Child and Adolescent Life in Health and Disease: A Study in Social Pædiatrics. By W. S. Craig, B.Sc., M.D., F.R.C.P.E. With a foreword by Professor Charles McNeil, M.A., M.D , F.R.C.P. Cloth. Price, $7. Pp. 667, with 202 illustrations. William Wood & Co., Mount Royal and Guilford Aves., Baltimore 2, 1946.

This excellent handbook of social pediatrics deals with the progressive development of social measures for the protection of British children in health and disease during the past three hundred and fifty years. It is of particular value as a source of reference at present, when the facilities for the medical care of children are being subjected to scrutiny with an effort toward betterment. Even though great progress has been made, the author points out the incompleteness of the program currently in effect. The scope of the text includes medical, social and educational measures and facilities, without undue emphasis on any single phase but with an attempt to integrate all services toward the safeguarding of the individual child. The need for projection of care through the period of adolescence is emphasized. From the medical point of view, special attention is directed toward available measures for the maintenance of child health, help for the handicapped, treatment of the sick and services for the medical care of certain conditions arising during childhood. Included with other valuable and interesting information in the appendix are data relating to facilities in representative British hospitals, convalescent homes and special schools both in the hospital and in the home. The book is written in an interesting manner and seems authoritative in its content. As is stated in Professor McNeil's foreword, it should be read by every one concerned with the care of children and adolescents, by all teachers of doctors, midwives or nurses who practice child care, and by all who devise and control the machinery of administration.

History of Medical Thought: An Essay. By Richard A. Leonardo, M.D., Ch.M , F.I.C.S. Cloth. Price, $2. Pp. 92, with 16 portraits. Froben Press. 4 St. Luke's Place, New York 14, 1946.

An apparent expansion of interest in the history of medicine may be the result of several factors. As has been evident in the past, periods of disturbance and uncertainty have not infrequently been associated with an awakened interest in the field of medical history—possibly as a mental refuge, possibly in the endeavor to understand the present in the framework of the past. Leonardo's essay on the history of medical thought is an illustration of this tendency. The title is well chosen, for the seven chapters give a succinct, well ordered and very readable survey of the mental approach of the physician to the clinical problem of disease during the centuries that have passed since Hippocrates. The author does not attempt a history of medicine and so the young student who wants to know the details of the development of the art and science of medicine will not be satisfied; but the physician who is still a student will find much of interest. Of course one may find statements, for instance that German medicine reached its height in the eighteenth century, to which one might take exception, but the treatise is well balanced and, despite the condensation, presents a fair evaluation of the great schools of medical thought. As such it will no doubt prove of real value. Sixteen portraits, some of which are not particularly relevant, are appended.

Bone and Bones: Fundamentals of Bone Biology. By Joseph P. Weinmann, M.D., and Harry Sicher, M.D. Cloth. Price, $10. Pp. 464, with 289 illustrations. C. V. Mosby Co., 3207 Washington Blvd., St. Louis 3, 1947.

It is unusual for a book of this nature to be the product of two physicians, one an anatomist, the other a pathologist, who are primarily associated with schools of dentistry. A tremendous amount of study, research and effort has been incorporated in it and the result is the best survey of bone biology, pathology and histology yet published. Confusion exists among bone pathologists, particularly with regard to the classification of tumors and the fate of aseptically necrotic bone. The authors present these controversial subjects in a simplified manner, and any student can understand the clear language used. The chapter on development of bones is concise, with an excellent conception of membranous and enchondral ossification. A large number of well chosen high power photomicrographs serve as unusually effective illustrations for the text material. The pathologic conditions presented are described and discussed in a brief and logical manner. The list of conditions discussed is not complete, but the authors make no claim for a textbook of bone pathology. This volume, however, is strongly recommended for all surgeons and students with an interest, academic or clinical, in bone and joint disease.

Manual de dermatología. Editado bajo los auspicios del Comité médico de la División de ciencias médicas del "National Research Council." Por Donald M. Pillsbury, M.D., Marion B. Sulzberger, M.D., y Clarence S. Livingood, M D. Cloth. Price, $7. Pp. 470, with 109 illustrations. M. V. Fresneda, Neptuno 561, La Habana, Cuba, 1947.

This is a translation by Roberto Quero, Havana, into Spanish of the English edition of the Manual of Dermatology issued during the war under the auspices of the Committee on Medicine of the National Research Council. The only addition by the translater to the original book is at the end of the chapter on dermatitis produced by plants, where he lists the Cuban plants capable of producing dermatitis.

Clinical Allergy: A Monograph on the Management and Treatment of Allergic Diseases for General Practitioners and Students of Allergy. By Alexander Sterling, M.D., assisted by Bea Sterling Hollander, A.B., M.D. Cloth. Price, $5. Pp. 198, with 16 illustrations. International Universities Press, 227 W. 13th St., New York 11, 1947.

The subject of allergy has grown so fast that no one book can be adequate. This book is small and consists chiefly of case reports. Some are very interesting while others are lacking in important details and are without definite etiologic factors. Much space is given to headings and subheadings, so that there really is but little information which a reader can glean from what little space is left. There are errors in spelling, and one glaring mistake is a statement that sensitivity to ragweed could not be transferred (in the original work of Prausnitz and Kustner). These two men lived in Germany, where ragweed is not a factor. The author is one of the pioneers in allergy and has contributed to its progress. He would have been well advised to undertake a larger work with more material and more suggestions for students and physicians. Authors of future small books on allergy should concentrate on one allergic condition.

A Directory of Agencies and Organizations Concerned with Rehabilitation and Services to the Handicapped. Compiled by Howard A. Rusk, M.D., and Eugene J. Taylor, M.A. Paper. Price, 10 cents. Pp. 133. New York Times, Times Square, New York 18, 1947.

This helpful publication gives the name, location, principal officers, history, services performed and publications of all important public and private agencies engaged in rehabilitation activities.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

STATUS ASTHMATICUS

To the Editor:—I would appreciate an outline and discussion of therapy for status asthmaticus, with special reference to the use of barbiturate sedation and meperidine hydrochloride (demerol).

Harry W. Orris, M.D., New York.

Answer.—The term status asthmaticus is generally used to designate a state of continuous asthma which fails to respond to routine treatment. The definite mechanism for this refractory state is not known. The seriousness of the condition demands experience and flexibility in the treatment of the various symptoms that may arise. Above all, excessive therapy must be avoided. It is commonly the case that epinephrine has been used excessively during the period preceding status asthmaticus. The patient in status asthmaticus is usually refractory to epinephrine, and its administration must be stopped for from twenty-four to forty-eight hours. To relieve the bronchospasm, aminophylline 0.25 to 0.5 Gm. given intravenously every three to four hours is frequently helpful The presence of anoxia may be helped by the administration of oxygen, especially if used with 80 per cent helium. For this a properly designed mask to prevent the loss of helium is helpful. The helium facilitates the absorption of oxygen. If the patient is dehydrated, either because of excessive perspiration or as result of vomiting, fluids should be given by mouth if the patient is able to retain them, or parenterally. The use of isotonic solution of sodium chloride intravenously or by hypodermoclysis may be indicated to replace the loss of chlorides if the patient has been vomiting excessively. In prolonged attacks it may be necessary to supply food by the use of 5 per cent glucose solution subcutaneously and by the use of amino acids intravenously.

Above all, rest is essential in severe status asthmaticus. The general relaxation produced by six to eight hours of sleep may result in considerable lessening of the severity of the attack, so that the patient responds to ordinary therapy. Rest is commonly obtained by the use of barbiturates in heavy doses. One should, of course, attempt to find out whether the patient is allergic to barbiturates, as may occasionally happen. It has been found advantageous to use chloral hydrate 1 to 2 Gm. by mouth or 2 to 4 Gm. by retention enema, repeated if necessary in four to six hours. This avoids the problem of barbiturate sensitivity and affords a reliable hypnotic. Paraldehyde is another useful drug that is effective. In severe cases 150 cc. of ether in an equal amount of olive oil administered slowly by rectal tube has been used to produce sleep, frequently with relief of the asthma. Neither meperidine nor morphine should be used in status asthmaticus because of the danger of respiratory depression. While some controversy exists on this question, the majority of allergists condemn the use of morphine because of its dangerous central action on the respiratory center. Meperidine has a similar action and, until experience with its use is much greater than it is at present, it should not be used in severe asthma. Unlike morphine, which acts to produce bronchospasm, meperidine produces bronchodilatation. This, however, is not sufficient to overcome its disadvantages as a respiratory depressant.

Status asthmaticus is a serious condition which cannot be treated according to any predetermined rule or rules. The physiologic balance of the patient may be disturbed in various ways. Some patients may require fluids, others may require salt. All patients with status asthmaticus require rest through carefully selected sedatives. The symptoms should be treated as they arise, and overtreatment must be avoided.

MANAGEMENT OF MENOPAUSAL SYNDROME AFTER BREAST CANCER

To the Editor:—Is estrogen contraindicated in treatment of a woman aged 45 with menopausal symptoms who had a radical mastectomy for carcinoma of the breast four years ago?

E. J. Levine, M.D., Chicago.

Answer.—The administration of estrogens to a menopausal patient with a personal history of cancer of the genital tissues such as the breast is definitely contraindicated. Estrogens may be sufficiently irritating to these tissues in sensitive persons so that a recurrence may be induced. The acceptance of this view has been substantiated by the therapeutic procedures now being investigated, such as removal of the ovaries of women with breast cancer if they are still menstruating, as well as the administration of androgens to women with this lesion to neutralize endogenous estrogens. The latter treatment is partially successful in alleviating the pain from metastases. Apparently, therefore, estrogens do have a varying but significant stimulating action on breast cancer. It is suggested that in order to obtain relief from the menopausal symptoms of such patients treatment with androgens such as methyltestosterone by mouth or testosterone propionate by injection be initiated. If these are not effective, sedation with the usual drugs may be of some benefit.

PRECIPITATE OR FUNGI IN VIALS OF HAY FEVER ANTIGEN

To the Editor:—I have noted a sediment in some vials of hay fever antigen and have been informed that it is a mold which contaminates the solution due to repeated punctures of the rubber stoppers by hypodermic needles. What kinds of molds would grow on such a simple medium, i. e. dust antigens in saline solution? Would any pathogenic fungi grow in this medium? What harm might come of an injection of material so contaminated?

M.D., Bronx, N. Y.

Answer.—It is possible for both nonpathogenic and pathogenic fungi to grow in the medium described. It is unlikely, however, that pathogenic fungi would find their way by a contaminating syringe. Naturally the possible ill results would depend mainly on the question of pathogenicity of the fungus; the saprophytes and the ordinary skin pathogens are the least harmful. It is suggested also that, unless bacteriologic investigation of the material has been made by one experienced in the recognition of fungi, it be not taken for granted that a sediment in such antigen solution is due to fungi. More often such sediment is due to the precipitation from the solution of one of the chemical ingredients, possibly polysaccharides.

POSSIBLE SYPHILIS WITH LIVER INVOLVEMENT

To the Editor:—A youth aged 18, seen on Jan. 1, 1947, complained of a weight loss of 14 pounds (6.4 Kg.), weakness and anorexia of four weeks' duration. Physical examination revealed only bilateral, discrete, pea size cervical, inguinal and axillary adenopathy. The liver edge was palpable two fingerbreadths below the costal margin and was slightly tender. The neurologic examination was negative. The complete blood count was normal. The urine was negative for bile. The urinary urobilinogen was normal. The quantitative blood bilirubin was less than 1.5 mg. per hundred cubic centimeters. The sulfobromophthalein liver function test (2 mg. per kilogram) showed 8 per cent retention in one-half hour. The twenty-four hour Hanger cephalin flocculation test was 4+ in twenty-four hours. The sedimentation rate was normal. The quantitative Kolmer reaction was 4+ (160 units). One month later the symptoms were unchanged, and the blood Kolmer reaction (state board of health) still showed a titer of 160 units. The spinal fluid examination, Wassermann reaction, cell count, protein and colloidal gold test were negative. A history of exposure could not be elicited. The mother recalled that at the age of 4 years the patient was taken care of by a colored woman who she later learned had received shots for a "blood condition." Beginning February 1 he received 4,800,000 units of penicillin over a period of one week at the rate of 600,000 units daily (Abbott's penicillin in oil, Romansky formula). This was followed by 2 cc. intramuscularly every five days of Squibb's iodobismitol. So far he has received eight injections. There has been a weight gain of 6 pounds (2.7 Kg.). The sulfobromophthalein test (5 mg. per kilogram) is now negative. The Hanger cephalin flocculation test shows no flocculation at the end of the forty-eight hour period, and the appetite has returned. The quantitative Kolmer remains at 160 units. The adenopathy is less and the liver edge is no longer palpable. Kindly discuss diagnosis and advise regarding additional treatment.

M.D., Kansas.

Answer.—The possibility that this is a case of syphilis with some liver damage at the commencement of therapy is good. To be considered among the diagnostic possibilities are (1) an infectious process involving the liver with a biologic false positive serologic test for syphilis, (2) a recently acquired syphilis with an acute syphilitic hepatitis and (3) a syphilis of long standing with gummatous or interstitial involvement of the liver.

Biologic false positive reactions associated with nonsyphilitic disease are apt to be of low titer and not sustained. While titers of the blood in acute infection in the absence of syphilis may reach levels greatly in excess of 160 units, these peaks are usually of short duration and trail off rapidly. Absence of change in titer in a month of observation is strongly suggestive of syphilis but is not in itself absolutely diagnostic. In the absence of other positive evidence of syphilis it is considered advisable to follow the blood serologic titer for a period of at least three or four months before coming to a final decision or instituting therapy.

In the present instance symptoms requiring treatment were present; it is to be presumed that the physical examination and ratory tests ruled out other diseases as far as it is possible to do so, under which circumstance the treatment given certainly seems justified. The articles by Moore, Eagle and Mohr (Suggested Method of Approach to Clinical Study of Biologic False Positive Test for Syphilis (The Journal, Nov. 9, 1940, p. 1602) and Beerman's more recent review (Biologic False Positive Reactions to the Test for Syphilis, *Am. J. M. Sc.* **209**:525 [April], **210**:524 [Oct.] 1945) are particularly good in giving the points which should be considered in ruling out the possibility of biologic false positive reaction.

Liver involvement from syphilis as far as it has been studied responds well to penicillin therapy. The article by Tucker and Dexter (Penicillin Treatment of Gummatous Hepatic Syphilis, *Arch. Int. Med.* **78**:313 [Sept.] 1946) should be consulted in this regard.

The clinical improvement in this case has apparently been satisfactory. The response of the serologic test is of less importance and will depend in large part on the stage of the disease when treatment was commenced, which is apparently unknown. The possibility of obtaining a negative serologic test will be good (at least a 70 to 80 per cent chance) if this is a recently acquired infection, but poor (not better than 50 per cent) if it is of long standing, irrespective of the type or amount of treatment. If the test does become negative as a result of treatment, the titer will gradually diminish and syphilis reagin will usually disappear from the blood some time between four and twelve months. If the patient is still seropositive at the end of one year, retreatment with at least the same and possibly with double the original dosage of penicillin could be considered.

Treatment other than this will depend largely on the confidence of the individual physician in the value of penicillin in the treatment of syphilis; here opinion varies because no one has used penicillin in cases such as described in sufficient numbers to come to a definite conclusion. There is some indication that the reinforcement of penicillin courses with metal chemotherapy is of value, but even this has not been well substantiated. Heavy metal therapy following a course of penicillin should be continued for at least eight to ten weeks. The treatment given this patient to date has been in accordance with accepted practice, and the penicillin dosage of 4.8 million units should be adequate according to our present knowledge, though some physicians give total dosages in the magnitude of 6 to 10 million units. The principal indication from now on is for periodic serologic tests using quantitative titer and physical reappraisal monthly for the next year and periodically thereafter for life. Additional treatment will have to be individualized and based on further developments.

MANOMETER FOR SPINAL FLUID PRESSURE

To the Editor:—Recently I bought a mercury spinal manometer. A few days later a neurologist told me that only the water manometer is reliable in recording cerebrospinal fluid dynamics. Is that true? What is the comparative efficiency between the mercury and the water manometer?

M.D., Pennsylvania.

Answer.—The water manometer is far superior to the mercury manometer for measuring spinal fluid pressures. This is true for several reasons. It is much easier to keep clean and is more readily sterilized. With the mercury manometer there are portions which cannot be sterilized, and the danger of contamination in using these parts is always present. Furthermore, the fluctuations on the mercury manometer are much less extensive than with the water manometer in view of the fact that mercury is some thirteen times heavier than water. For the same reason the responses to changes in pressure are registered much more slowly with the mercury manometer. There is no longer any excuse for using such an inefficient and unsatisfactory apparatus as the mercury spinal manometer. The aneroid spinal manometer, which is seldom seen in this country, is as unsatisfactory as the mercury manometer.

WATER SOFTENING CHEMICALS AND DERMATITIS

To the Editor:—Please give me information concerning the possibility of commercial water softening chemicals causing dermatitis or pruritus vulvae or pruritus ani.

M.D., Missouri.

Answer.—Chemicals used for softening water are usually fairly strong alkalis. Sodium carbonate, trisodium phosphate, ammonium carbonate, sodium metaphosphate, sodium metaborate, sodium phosphate, sodium aluminate and sodium hexametaphosphate are some of the chemicals most often found in water softeners.

Some special formulas also contain sodium silicate, calcium chloride and sodium fluoride. Many of these chemicals are primary irritants in powder or granular form and in strong solution. When used to soften water they are used in proportions of the order of 1:1,000 or 1:10,000, depending on the "hardness" of the water. Such dilutions should not cause the symptoms described except perhaps in those who are extremely sensitive.

It is possible to carry the powdered softeners to the vulva and anus by contaminated fingers. It is also possible that underclothes washed in strong solutions of the softeners may retain a sufficient amount to cause skin irritation.

FLUID INTAKE IN CONGESTIVE HEART FAILURE

To the Editor: I read the article by Wheeler, Bridges and White in The Journal of Jan. 4, 1947 with interest. With regard to the treatment of congestive heart failure with a diet low in salt and liberal intake of water, I believe that the restriction of liquid in heart failure is based on the belief that the work of the heart is thus reduced—a kind of heart rest prescription. Would you please discuss this physiopathologic question?

M.D., Lisbon, Portugal.

Answer.—Undoubtedly the chief two reasons for the traditional restriction of fluid intake in the presence of congestive heart failure have been (1) the fear of further water-logging and (2) the extra work for the heart in pumping additional fluid. However, both these fears have proved unjustified. In the first place, the difficulty is brine-logging and not water-logging, and, secondly, there seems to have been no difficulty, so far as the additional work of the heart is concerned, by the giving of a considerable amount of fluid daily to patients with congestive heart failure provided the sodium intake is kept low. The extraordinary ability of the circulation to handle considerable amounts of fluid taken in, in the face of congestive heart failure, has been an agreeable surprise to most of those interested in the subject.

PHYSICAL THERAPY FOR HEAD INJURIES

To the Editor:—In injuries of the head there have been various opinions as to the value of physical therapy. Some neurologists favor it; others do not. If it is indicated, what form of physical therapy is desirable? I have in mind chronic cases initiated by a contusion of the head, with or without a concussion. In fractures of various parts of the extremities and back, infra-red and short wave is a standard form of treatment. Should it be given in fractures of the skull?

Nathan Tandet, M.D., New York.

Answer.—This question is hardly specific enough to permit a brief answer. To ask about the value of "physical therapy" is comparable to asking about "the value of medicine" or "the value of surgery."

Physical agents employed in the expanding field of physical medicine are so varied that it is impossible to describe all of them and to discuss the possibilities of their employment in injuries of the head. Applications of heat in the form of infra-red radiation or short wave diathermy to simple contusions of the head may be made, as is the case with contusions in other regions of the body twenty-four to forty-eight hours after injury.

Superficial applications of heat are employed sometimes in the management of fractures of the extremities largely to overcome impairment of function in the surrounding muscles and tendons which may have been damaged incidentally. In fractures of the skull, such impairment of function of muscles and tendons does not usually exist. Intensive heating of bony tissue in any region may delay union of fractures. Therefore applications of heat in fractures of the skull are indicated less frequently than in fractures of the extremities.

CORRECTION

Vaginal Douching.—In the letter to the Editor entitled "Vaginal Douching," from Dr. Karl J. Karnaky in Queries and Minor Notes, The Journal, Aug. 16, 1947, p. 1446, the figures for the number of "times less (or more) acid than normal" were incorrect. The correct figures are given in the tabulation below, together with the *p*H values reported in the letter. These figures are based on the relative hydrogen ion concentrations of the vaginal mucosa as calculated from the *p*H values reported.

*p*H	Acidity Relative to Normal (*p*H = 4.36) (Ratio of Hydrogen Ion Concentrations)
4.36 (normal)	1.00
4.49	1.35 times less acid
6.00	43.70 times less acid
5.59	17.00 times less acid
6.61	177.50 times less acid
5.62	18.20 times less acid
4.57	1.62 times less acid
7.45	1,230.00 times less acid
6.72	228.50 times less acid
4.20	1.44 times more acid

THE PRESENT STATUS OF ANESTHESIOLOGY AS A SPECIALTY

Chairman's Address

CHARLES F. McCUSKEY, M.D.
Los Angeles

Anesthesiology has developed slowly into a medical specialty. Before the establishment of the American Board of Anesthesiology the physician who devoted his full time and effort to the practice and advancement of anesthesia as part of the practice of medicine was rare except in a few localities. The New York Society of Anesthesiology and International Anesthesia Research Society contributed much to the development of this specialty by helping to bring together and unite anesthesiologists in the American Society of Anesthesiologists. With the formation of the American Board of Anesthesiology and the Section on Anesthesiology of the American Medical Association the specialty has been firmly established in the practice of medicine. Much remains to be accomplished before it reaches full maturity.

The excellent work of anesthesiologists in the recent war in reducing mortality through proper care in the operating room has been reflected in the present demand for anesthesiologists in civilian practice. To supply this demand with trained qualified specialists is one of the urgent tasks at present. As this immediate demand is met, it will create new demands for universal recognition of the part of the anesthesiologist in the medical world, which awaits only demonstration of his service.

At present there are 337 diplomates of the American Board of Anesthesiology and 261 fellows in Anesthesiology of the American Society of Anesthesiologists. This does not mean 598 diplomates or fellows, because many members of this group hold dual certification. There are 2,400 members of the American Society of Anesthesiologists. Many of these do not limit their practice to anesthesiology, and some do not practice at all but are engaged in teaching the basic sciences or in research. The American Medical Association has approved 102 hospitals for the training each year of a total of 366 residents in anesthesia. Against this small total of actual and potential anesthesiologists there is a total of 6,280 hospitals in the United States. Of this number, those classified as general hospitals, children's hospitals, orthopedic hospitals, eye, ear, nose and throat hospitals and tuberculosis hospitals total 5,278. The majority of these 5,278 hospitals are without proper or adequate coverage by anesthesiologists. The situation is further complicated by the fact that a concentration of anesthesiologists exists in the larger cities and in teaching centers.

With this tremendous potential need for the services of anesthesiologists a large number of young physicians should be turning toward this specialty. However, this is not the case. Some of the factors that may be responsible are as follows: 1. The importance of anesthesia in the surgical care of the patient is not stressed in the medical schools, and the majority of medical students are not given adequate instruction in the basic principles and problems of anesthesia. 2. Because of the lack of anesthesiologists in most communities, anesthetics have been given by general practitioners, surgeons and technicians. Interns who receive training in these hospitals are never exposed to the practice of anesthesiology in its best form and hence are not attracted to it. 3. The surgeons in localities where there are no anesthesiologists are responsible for anesthesia as well as for surgery. This situation has tended to suppress anesthesiology as a separate specialty. 4. Because anesthesia in many localities is given largely by trained technicians hired by the hospital the physician has not been given any particular financial inducement to practice this specialty. The profit accruing to hospitals from the use of technicians has caused some hospital administrators to oppose the use of the anesthesiologist who is a medical specialist despite the fact that physicians can give the patient better medical care.

These then are some of the obstacles confronting anesthesiology as a specialty at present. Many surgeons because of these factors have never seen good anesthesia. Therefore they do not demand it or expect it. The younger surgeons who have been in the army or navy are just now beginning to voice their discontent with the present situation.

On the other side, let me consider some of the more favorable factors. Despite obstacles, inertia and discouragement anesthesiology is a growing specialty. It has grown slowly to the present, but everything indicates that its growth will be rapid in the future. In many centers it is an active specialty, the value of which has been firmly established through the efforts of a few teachers and excellent clinicians. Younger men have developed in these localities, and they in turn are becoming the nucleus for future centers. Surgeons who have been in the services and have had the benefit of an anesthesiologist as a consultant and co-worker are making maximal use of such specialists in their localities and doing much to foster and encourage them to locate in communities in which they are not as yet prevalent. Members of hospital staffs are insisting that anesthesiologists be secured to give the patients the maximal possible benefits of good surgical care. Resi-

s who have finished with their training in anesthesiology are in great demand and become established rapidly and successfully. Many of these physicians have been started on their careers in anesthesiology in the army or navy and have continued in this specialty because they realize its future. That so many have remained is proof that if an adequate understanding of the field develops one of the major problems of the specialty is solved.

I have considered some of the adverse and some of the brighter aspects facing the anesthesiologist, and now I wish to consider what more can be done to improve the specialty and to advance it. It seems to me that each anesthesiologist must be a teacher. He must teach surgeons, residents, interns, medical students, nurses and the laity what he represents and what he can do to lessen the burden of illness for the patient. The anesthesiologist must also be a clinical physiologist. It is not enough for him to be highly skilled in the art and science of anesthesia; he must appreciate and take into account the variables that each patient presents as a physiologic entity. The anesthesiologist, of course, should always be a physician. As such he takes the personal interest in each case that is characteristic of the practice of medicine as it is fostered by the American Medical Association.

CARCINOMA OF THE STOMACH

A Ten Year Survey (1936 to 1945 Inclusive) of Early and Late Results of Surgical Treatment at the University of Minnesota Hospitals

DAVID STATE, M.D.
GEORGE MOORE, M.D.
and
OWEN H. WANGENSTEEN, M.D.
Minneapolis

Cancer ranks second only to cardiovascular disease as the commonest cause of death in this country. Of all deaths due to carcinoma, one fourth to one third are due to gastric cancer. As the age of the population increases, the number of persons who die from gastric carcinoma will also grow larger, so that by 1960 it has been estimated that 40,000 patients will succumb to gastric carcinoma annually.[1]

The very frequency of gastric cancer suggests that any approach to the problem of reducing the death rate from malignant growths must include a serious consideration of how the number of persons who die from gastric cancer may be diminished.

In the course of outlining a study to determine likely precursor groups of gastric carcinoma,[2] it was considered that the results of therapy of this disease at this institution during the preceding ten years should be determined so as to provide a basis for comparison with future studies.

REVIEW OF THE LITERATURE

An exhaustive review of the world literature on the end results of treatment of gastric carcinoma up to 1937 has been compiled by Livingston and Pack.[3] The large experience of the Mayo Clinic has been summarized by Walters, Gray and Priestley.[4] More recently Maimon and Palmer,[5] in addition to summarizing and analyzing their results at the University of Chicago, have brought the literature on this topic up to date. These authors have called attention to wide variations in the published data from various institutions and have emphasized the need of analyzing all published statistics with respect to four factors: (*a*) the total number of patients with gastric cancer; (*b*) the number of patients subjected to operation; (*c*) the number of patients in which a gastric resection was done, and (*d*) the number of survivors in relation to the total.

Our data analyzed according to these headings are herewith presented.

OBSERVATIONS

(*a*) *Total Number of Patients with Gastric Carcinoma.*—The total number of patients with gastric carcinoma seen at the University of Minnesota Hospitals over the ten year period studied (1936 to 1945) was 586. Of these, 432 were men and 154 women. The average age (chart 1) was 63.2 years. Of this group, 19 patients were in terminal stages of their disease when first seen but are included in the statistical data.

(*b*) *The Number of Patients Subjected to Operative Intervention.*—The number of patients operated on was 447, an operability rate of 76.3 per cent (table 1).

If the 19 patients who were in terminal stages on admission are excluded, the operability rate becomes 79 per cent. In this group of 447 patients 85 (14.5 per cent) had exploratory laparotomy only, 25 (4.3 per cent) had gastrojejunostomy and 30 (5.1 per cent) had enterostomy.

(*c*) *The Number of Patients in Whom Gastric Resection Was Accomplished.*—Three hundred and seven patients underwent gastric resection, a resectability rate of 52.2 per cent. In this group there were 31 total gastric resections and 276 partial resections. The resectability rate based on the total number of patients studied was 52.2 per cent, but when determined on the basis of those subjected to laparotomy (447) it was 68 per cent.

Postoperative Mortality.—There were 307 gastric resections (table 1) with 51 deaths, a mortality of 16.6 per cent. There were 276 partial gastric resections with an operative mortality of 15.2 per cent and 31 total gastric resections with an operative mortality of 30 per cent. We have not subdivided our cases of gastric resections into those which were simple and those which were more complicated. Sixty-five per cent of all resected cases, however, had metastases to the regional lymph node and/or extension of the carcinoma to other organs, necessitating extensive surgical procedures.

Those operative procedures which were purely palliative carried with them a not insignificant mortality.

Read before the Section on Surgery, General and Abdominal, at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1947.

[5] Maimon, S. N., and Palmer, W. L.: Gastric Cancer: Laparotomy, Resectability and Mortality, Surg., Gynec. & Obst. 83: 180, 1946.

There were 85 exploratory laparotomies performed with a mortality rate of 8.2 per cent, 25 gastrojejunostomies with a mortality rate of 24 per cent and 30 enterostomies with a mortality rate of 13.4 per cent. These high figures are similar to those reported by other authors (Maimon and Palmer,[5] Livingston and Pack[3] and Anschütz[6]), and since the degree of palliation by operative procedures other than gastric resection is so small (vide infra), it is obviously desirable to perform a gastric resection even for palliation whenever feasible.

Causes of Postoperative Mortality After Gastrectomy.—There were 51 deaths after gastric resection, and it was possible to obtain autopsies in 44 of these cases. The major cause of death (table 2) was peritonitis, which accounted for 28 fatalities. Eight patients succumbed to pulmonary complications (atelectasis and pneumonia); 4 died of cardiac failure, 3 of renal complications, 2 of pulmonary embolism, 1 of a cerebrovascular accident and 1 of shock; in 4 cases the cause of death was undetermined.

It is not surprising to note that the most frequent cause of death after operation was peritonitis. Whereas the closed method of gastric resection was begun in this clinic in 1938, it was not until 1940[7] that every member of the surgical staff was employing the method. Moreover, it probably should also be said that every surgeon trained in this clinic since the closed method of resection was adopted has remained an advocate of the closed anastomosis.

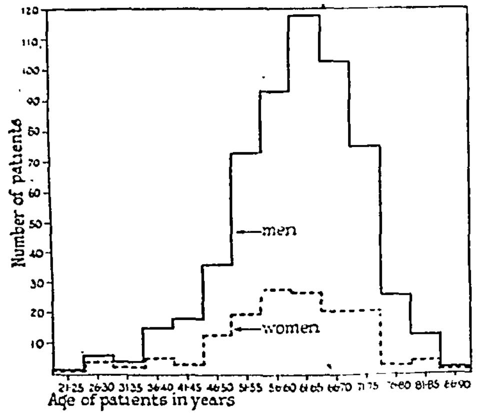

Chart 1.—Age and sex incidence of carcinoma of the stomach.

Since 1940 peritonitis has been infrequent indeed after simple gastric resection for cancer. The majority of the instances occurred after total gastrectomy or after complicated gastric resection which necessitated simultaneous excision of adjacent organs such as liver, pancreas and the colon. One patient died of a biliary peritonitis; at operation the gallbladder had been excised together with the gastric cancer. At autopsy the source of the leak of bile could not be demonstrated, but it was believed to have occurred from a small biliary duct in the hepatic margin adjacent to the wall of the gallbladder.

A baffling problem has been the management of the pancreas after partial division. In the main, most members of the surgical staff favor closure without drainage. Isolation and ligature of the pancreatic duct, employing a hand lens if need be to find it, is important. Approximation of the edge of the divided pancreas with a row of interrupted fine silk suture (0000) is regular practice, observing care to cut away all pancreatic tissue above the clamp. Finally, additional covering of the divided pancreas away from the gastrointestinal suture line is also important. Interestingly enough, after total gastrectomy with simultaneous division of the vagus nerves, less difficulty attending simultaneous resection of the pancreas seems to have occurred than after partial gastric resection. The preservation of the vagal trunks as well as partial retention of the secretal influence in partial gastric resection is probably responsible for this difference.

TABLE 1.—*Mortality of the Various Operative Procedures*

	No. of Patients	Per Cent of Total	Operative Mortality
Patients with no operation	133	23.7	
Laparotomy only	85	14.5	8.2
Palliative procedures:			
(*a*) Gastroenterostomy	25	4.3	24.0
(*b*) Enterostomy	30	5.1	13.4
Resections:			
(*a*) Partial	276	47.1	15.2
(*b*) Total	31	5.1	30.0
(*c*) All types	307	52.2	16.6
Total operations	447	76.3	17.9

The Fate of Patients Surviving Gastric Resection.—It was possible to determine the fate of each of the 307 patients subjected to gastric resection.[8] Two hundred and fifty-six patients survived operative treatment, but it is only those patients operated on prior to 1943 that one can speak of as three year cures; and only those patients operated on prior to 1942 can be considered 5 year cures. Table 3 *A* indicates the number of patients who survived for three years after gastric resection in the years 1936 to 1943. The percentage based on the total number of patients examined averages 10.7 per cent, but based on the number of those subjected to gastric resection the percentage of 3 year survivors reaches 29.4 per cent, with a high of 45 per cent for 1937. In all, 47 patients survived three years.

TABLE 2.—*Cause of Death Following Gastrectomy (All Types)* *

Peritonitis	28
Pulmonary complication	8
Cardiac failures	4
Renal complications	3
Pulmonary embolism	2
Cerebrovascular accident	1
Shock	1
Undetermined	4
Total	51

*Forty-four autopsies obtained.

Table 3 *B* indicates that 22 patients of the 328 patients seen between 1936 and 1941 inclusive survived five years, an incidence of 6.6 per cent based on the total number of patients seen. However, if calculated on

basis of those patients who survived resection (102 patients) the percentage of five year survivors becomes 21.5.

[8] We are indebted to the referring physicians who responded to our requests for follow-up on patients and in particular to members of the Department of Vital Statistics of the Min[illegible] State Public Health Department who traced a *substantial n*[illegible] *patie*[illegible] *that our follow-up was complete.*

Lymphosarcoma of the Stomach.—In addition, 5 patients with gastric lymphosarcoma, not enumerated among those with carcinoma of the stomach, were treated at this clinic between 1936 and 1945. One patient was deemed inoperable at laparotomy and was given deep roentgen therapy following operation. The fate of this patient was not determined because he could not be traced. The remaining 4 patients underwent partial gastric resection. There was no operative mortality in this group. In addition to subtotal gastric resection, 1 patient had postoperative radiation therapy. She is alive and well, now nine years later. The other 3 patients did not receive radiation therapy. Two patients survived one year after operative treatment, and the third is alive and well five years after surgical therapy. This experience is in keeping with that of others, which suggests that the incidence of long time survivors is greater after gastric resection for lymphosarcoma than it is for carcinoma.

Table 3.—*Survival of Patients Operated On in the Years 1936 to 1943 Inclusive*

			A			B		
			Patients Surviving 3 Yr.			Patients Surviving 5 Yr.		
Year	Total No. of Patients	No. of Gastric Resections	No.	%	% of Those Surviving Gastrectomy	No.	%	% of Those Surviving Gastrectomy
1936	58	16	4	7.0	40.0	1	1.7	10.0
1937	47	17	5	10.0	45.0	4	8.5	30.7

TREND IN OPERABILITY, RESECTABILITY AND MORTALITY OVER THE TEN YEAR PERIOD

Chart 2 indicates that from 1936 to 1945 there has been a definite increase in the operability and resectability rate and a pronounced drop in the postoperative mortality. Whereas in 1936 the operability, resectability and mortality rates were 57, 28 and 25 per cent, in 1945 these rates were 88, 80 and 4.9 per cent. If the resectability rate is determined on the basis of the number of patients explored, in 1936 it was 48 per cent whereas in 1945 it was 89.7 per cent. The mortality rate in 1945 is for both subtotal and total gastric resections. The mortality after partial gastric resection alone was 3.8 per cent. There were 9 total gastric resections in 1945 with 1 death, a mortality rate of 11.5 per cent. Thus, of the 58 patients examined in 1936 only 10 were given a chance at cure or palliation, while in 1945 of 77 patients seen 58 were given that chance. Approximately twenty different surgeons performed the gastric resections in the ten year period (1936 to 1945) studied. Similarly, the resections in 1945 were done not by any single individual or team but were performed by seven different members of the surgical staff.

Although comparison between the years 1936 and 1945 is striking, it can be observed that during the last four years the operability rate has been considerably higher than 80 per cent, and of those patients subjected to laparotomy an average of 76 per cent have been resected (chart 3).

The decrease in operative mortality since 1940 has been due, we believe,[9] to a number of factors such as (1) routine employment of the aseptic or closed method of gastric resection; (2) elimination of obstruction at the efferent outlet stoma as a postoperative complication; (3) better preoperative nutritional preparation of the patient; (4) improved postoperative care, including early ambulation; (5) better anesthesia, and (6) in the last few years, availability of antibiotics, especially penicillin.

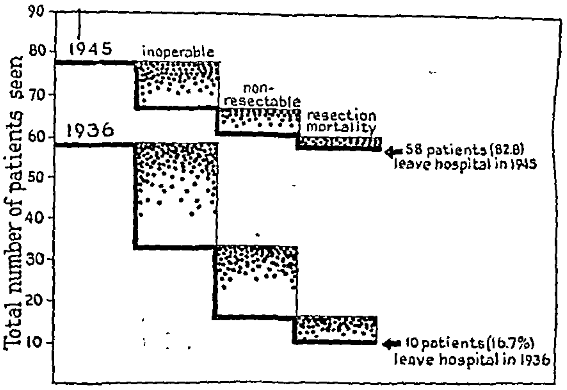

Chart 2.—Comparison of efficacy of surgical therapy of gastric carcinoma in 1936 and 1945.

PALLIATIVE OPERATIONS FOR CARCINOMA OF THE STOMACH

(*a*) *Gastrojejunostomy and Enterostomy.*—During the earlier periods of this study (1936 to 1938) 5 gastrojejunostomies were performed for feeding purposes in apparently operable lesions. In only 1 of these cases was a resection performed at a later date; the others on subsequent exploration (three months) were considered inoperable. In all, the average length of survival after the 25 gastrojejunostomies which were performed was 5.4 months. Enterostomy, which was done in 30 patients, offered only an average of 3.5 months of survival with little or no palliation.

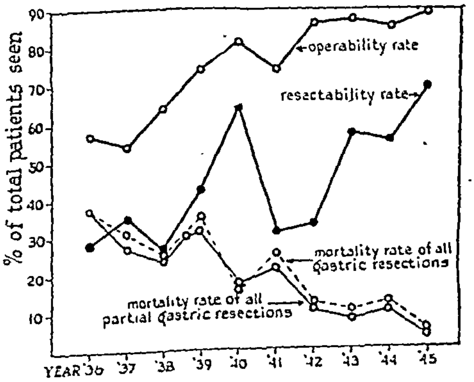

Chart 3.—Ten year trend of operability, resectability and mortality rates in the treatment of gastric carcinoma.

(*b*) *Gastric Resection.*—It is apparent that with the high resectability rate presented from this clinic, a large number of gastric resections were performed

---

9. Wangensteen, O. H.: The Surgical Problem of Gastric Cancer, Arch. Surg. 46: 879, 1943.

not with the idea of curing the patient (because the extent of the carcinoma precluded this) but with the express purpose of offering worth while palliation. It is obvious that other palliative procedures such as gastrojejunostomy and enterostomy seldom benefit the patient at all, for the average survival of persons who do not have any treatment after the diagnosis of carcinoma of the stomach has been made is approximately three months. The number of months of palliation in those patients who survived gastric resection between the years 1936 and 1943 but subsequently expired from carcinoma of the stomach averaged approximately 22.4 months. In the main, the patients were reasonably comfortable during this interval up until a few weeks prior to their death. Sufficient time has not elapsed to permit the determination of the degree of palliation obtained in operations performed since 1943.

(*c*) *Palliation in Presence of Metastases of the Liver.*—Patients have had gastric resections for carcinoma even in spite of evident metastases of the liver. In most instances the resection was performed because of high grade obstruction to the gastric outlet. The average number of months of palliation has been much higher than we anticipated, namely fifteen months.

COMMENT

The Present Survey.—The trend in this clinic has been to increase the rate of operability and resectability, so that in 1945 the operability rate was 88 per cent and the resectability rate 79.6 per cent. These figures compare favorably with those published elsewhere, for the highest operability rate of 89.9 per cent was reported by Bocharov,[10] and the previous highest resectability rate of 44.6 per cent was published by Lahey.[11] A high operability and a high resection rate are of the greatest significance, for it is only when the patient is subjected to operative therapy and the tumor in the stomach is removed that he has a chance of survival. A low operability and resectability rate, even in the presence of an exceedingly low mortality rate, will do little to improve the end results of treatment directed at carcinoma of the stomach.

The postoperative mortality rate in this clinic has also decreased during the period of study, so that even in the presence of a rising operability and resectability rate the mortality after gastric resection (subtotal and total) for the last four years has been under 10 per cent and for 1945 was 4.9 per cent.

The patients who survived three and five years constitute only a small proportion of the patients seen. There can be no question, however, even if these patients be cured of their disease, that periods of palliation averaging up to 22.4 months constitute a worth while achievement for the patient. Surprising, too, have been the prolonged periods of palliation following gastric resection even in the presence of evident metastases of the liver (average survival fifteen months).

It is questionable whether the operability, resectability and mortality rates that have been reported for 1945 will be bettered appreciably in our hands. It becomes evident that the only way in which the end results may be improved is by earlier diagnosis. Livingston and Pack,[2] as well as Walters, Gray and Priestley[4] have shown that if gastric resection can be done when the carcinoma of the stomach is entirely confined to that organ, the five year survival rate reaches 55 per cent. Moreover, Berkson[12] has indicated that after five years the survival expectancy is the same as that for well persons of the same age. To attain consistently high rates of cure, it is evident that the surgeon must have access to patients in whom the disease has not made such extensive progress. From our experience with patients who have residual carcinoma in the proximal line of resection, following gastrectomy, there is an interval of approximately fifteen months before the patient has symptoms of recurrence; in some patients it is longer. This has led us to believe that carcinoma of the stomach may be a silent disease for a period of fifteen to twenty months; and for another four to six months the symptoms may be so vague that the patient fails to seek medical aid. Moreover, if he does, the physician may fail to think that there is need to obtain a roentgenogram of the stomach. In consequence the diagnosis toc often is delayed until the patient's chance of cure is poor.

Improvement in Operative Technics.—It is our impression that the more complete operation performed today routinely in this clinic for all operable gastric cancers will be followed by a somewhat larger number of long time survivors.[13] In such an operation the following factors are important: (1) extensive excision of the stomach with complete removal of the entire lesser curvature together with a segment of the duodenum and (2) excision of the greater omentum as well as the entire gastrohepatic omentum, including that segment of it which envelops the right side of the subdiaphragmatic esophagus. In lesions with local extensions to other organs such as the pancreas, transverse mesocolon or colon, simultaneous excision of such involved structures is indicated. Whether total gastrectomy will improve materially the results of operation remains to be shown. To be certain, if recurrence in the residual gastric pouch were a common sequel of subtotal gastric resection for cancer, Longmire's[14] suggestion of substituting total gastrectomy for partial gastric resection would be well worth heeding. Moreover, the operation of total gastrectomy can now be performed in practiced hands with a reasonable mortality. By the employment of the simple expedient of anchoring the posterior esophageal wall to the jejunum by two rows of interrupted silk sutures, the first row being placed at the mesenteric border of the jejunum,[13a] a firm buttress for the additional anastomotic row of sutures is obtained. When the anterior suture is completed the use of the anterior peritoneal flap described by Lahey[15] (1938) together with the posterior esophagojejunal fixation insures complete covering (extraperitonealization) of the anastomosis.

Tardiness of Diagnosis.—Measured against the broad background of gastric cancer, the increased salvage of life which will result from improvements in operative technics probably will not be large. It is perhaps permissible to suggest, however, that the only optimistic feature of the present outlook in the problem of gastric gnancy is what can be done surgically for those ho suffer from gastric cancer. The surgeon's lament is that he sees too many patients too late. Yet this is the complaint of every surgeon dealing with malignant visceral growths. It has taken a long time to bring surgical practice to its present level of accomplishment, as this year, marking the Centennial of the origin of the American Medical Association, suggests. Looking back, mindful of the items that have made the surgical treatment of visceral cancer not alone possible but safe, one cannot help but ask, why did it take so long? Discovery is a slow and painstaking process, in which every increment of gain in knowledge in one art or science is dependent on similar gains in related fields.

[15] Lahey, F. H.: Complete Removal of the Stomach for Malignancy with the Report of Five Surgically Successful Cases, Surg., Gynec & Obst. **67**: 212, 1938.

However much we have occasion to deplore the tardiness of diagnosis of gastric cancer, the general improvement which has attended the efforts of the surgeon in his wrestle with the hazards of operation should cause us to have more patience with our own inability to diagnose gastric cancer early. Visceral cancer is a silent disease. Although we lament that patients fail to heed the onset of symptoms, our primary concern in the detection of gastric cancer should be with the circumstance that visceral cancer is a silent disease. The interval of transition in the cells of a mucous membrane or epithelial surface from the normal to a [illegible]nt state is a slow and gradual process, as sug[illegible] the observations of Broders[16] for several types of malignant tumors and by Mallory[17] for gastric neoplasms; moreover, symptoms ordinarily are delayed till the invasive phase of the malignant transformation begins to compromise the function of the organ involved.

Cancer Detection Clinics.—With the knowledge of these facts and circumstances, and mindful of the alarmingly frequent incidence of visceral malignancy, and in particular of gastric cancer, it would appear that the only helpful method of recognizing visceral cancer earlier would be to examine periodically by the most precise means available a population believed to be normal, beginning at that time of life when visceral cancer is definitely on the increase. Autopsy figures suggest that 1 woman in 20 beyond 40 years of age will die of gastric cancer and that 1 of 12 men past 50 years of age will fall victim to the ravages of cancer of the stomach.[18]

A few pilot plants set up as Cancer Detection Clinics could probably determine within the space of five years the efficacy of available diagnostic agents in disclosing the presence of silent cancers in persons who do not recognize that they are ill. Obviously the time has not yet come to explore this thesis on a wide base. There are numerous persons who decry this approach to the problem as involving much labor and cost and little reward. To many, this prospect appears even less promising than David setting out against Goliath with a sling shot. Those armchair philosophers would prefer to wait till the dreams of a discerning Joseph or a Daniel divine new approaches to the detection of gastric cancer.

The surgeon who has made visceral cancer his concern is not a person to be readily dismayed. If as great an advance can be made in the early detection of gastric cancer during the next decade as has occurred in its surgical management during the last ten years, the members of the medical profession will have good reason to feel hopeful that a brighter day is dawning for the sufferer from gastric cancer. The surgeon knows from his own experience that consistently earlier diagnosis would change completely for the better the present dismal outlook in visceral cancer.

In this clinic we have been examining over a two year interval the likelihood of uncovering in the outpatient population of a University Hospital Dispensary patients who harbor precursors of gastric cancer.[2] In this group have been included (1) all men and women over the age of 50 with (*a*) histamine achlorhydria or hypochlorhydria (less than 30 degrees free acid), (*b*) unexplained anemia (less than 10 Gm. hemoglobin per hundred cubic centimeters) and (*c*) occult blood in the stool; (2) the relatives of patients with gastric carcinoma; (3) all patients, regardless of age, with pernicious anemia, and (4) patients with gastric polyps. (5) The patient with free hydrochloric acid and a defect believed to be a gastric ulcer belongs in this precursor group, in that it is virtually impossible in many instances to determine whether the lesion is benign or malignant. Up to Nov. 1, 1946, 1,253 patients were subjected to gastric analysis employing histamine, and of this number 691 fell into the precursor group study. Roentgenograms were obtained in 575 patients, and 2 silent carcinomas and 15 gastric polyps were found. Moreover, the silent gastric cancers disclosed were not early lesions. The most promising aspect of the study would appear to be the location of the gastric polyps, some of which will undoubtedly become malignant with the elapse of time.

SUMMARY

1. Over a ten year period (1936 to 1945 inclusive) 586 patients with gastric carcinoma were seen in this clinic. Nineteen were in terminal stages of the disease when first seen.

2. Four hundred and forty-seven of this group of 586 patients were operated on, an operability rate of 76.3 per cent.

3. Gastric resection was performed in 307 patients; in 31 a total gastric resection was done, and in 276 a partial gastric resection was accomplished. The resectability rate based on the total number of patients seen (586) was 52.2 per cent, but based on the number of persons explored (447) it was 68 per cent. The previous highest resectability rate was 44.6 per cent reported by Lahey[11] (1940).

4. The mortality for all gastric resections was 16.6 per cent. For partial resections it was 15.2 per cent, and for total gastric resections it was 30 per cent.

5. The chief causes of death postoperatively were (in order of frequency) peritonitis, pulmonary complications, cardiac failure, renal complications and pulmonary embolus. In 4 instances the cause of death was undetermined.

6. Because sufficient time has not elapsed, the percentage of patients surviving three and five years can only be determined in relation to those patients operated on in the periods 1936 to 1943 and 1936 to 1941. The percentage of patients surviving three years after gas-

trectomy was 10.7 per cent, but based on the number of patients subjected to gastric resection it was 29.4 per cent. The percentage of patients surviving five years was 6.6 per cent, but determined on the basis of the number of patients surviving gastric resection it was 21.5 per cent.

7. Gastric resection was the only palliative procedure of value. The average number of months of palliation following gastric resection was approximately twenty-two. The patients in the main were comfortable up to the last few weeks before their death.

8. The operability and resectability during the ten years of study have increased steadily, while the mortality has decreased markedly. In 1936 the operability and resectability rates were 57 per cent and 28 per cent, whereas in 1945 these rates were, respectively, 88 and 80 per cent. The resectability rate for 1945 based on the number of patients explored was 89.7 per cent. The mortality rate for partial gastric resection in 1936 was 25 per cent, while in 1945 it was 4.9 per cent, which figure includes both total and subtotal gastrectomy.

CONCLUSIONS

1. Gastric resection remains the only mode of treatment capable of curing gastric carcinoma.

2. In spite of an increasing rate of operability and resectability and a decreasing mortality rate, the total number of patients cured of gastric cancer remains limited. In a series such as this, in which the number of palliative resections is large, the percentile of ultimate cures in the resection group obviously will be lower than if the indications for resection had been more conservative. The longest possible extension of life, however, results from employment of liberal interpretation of justifiable indications for even palliative resection. And until earlier recognition of gastric cancer makes curative operations more frequent, surgeons must continue to offer temporary relief when the hope of lasting cure is gone.

3. In order to increase appreciably the number of patients cured of gastric carcinoma, it is mandatory that the diagnosis be made at an earlier period than it is being made now. Efforts at detection of gastric visceral cancer, though they involve much labor and cost and little immediate prospect of reward, should be encouraged, for until our knowledge of the origins of cancer teaches us how to prevent or arrest its development, the only manner in which an important impact can be made on the problem in our own generation is through the agency of earlier diagnosis.

ABSTRACT OF DISCUSSION

Dr. George T. Pack, New York: At the Memorial Hospital, Dr. Gordon McNeer and I analyzed the results of treatment of gastric cancer during the same decade, and our statistical data are practically identical with those furnished by Dr. Wangensteen. The statistics from the Memorial Hospital represent the operative mortality for all cases including the junior attending and resident staff. The high mortality rate consequent to gastroenterostomy for cancer is universal throughout the world. It is usually greater than the rate for resection because of the more advanced stage of the disease. Of our patients surviving gastric resection for cancer more than five years, in only 1 did a recurrence develop, which unusual fact is not in keeping with the frequency of recurrence of cancer after five years in other regional and histologic types. In the table listing the cause of operative deaths Dr. Wangensteen, who is the leading advocate of the closed or aseptic method of anastomosis after gastrectomy, has given peritonitis as the most frequent cause of death. At the Memorial Hospital the commonest fatal complications were of pulmonary and cardiovascular nature. Peritonitis has been a relatively infrequent, although important, cause, and yet we use the open method of anastomosis as a routine procedure. Dr. Wangensteen's figure for resectability is 52 per cent, which is 17 per cent higher than our resectability rate of 35 per cent. Yet our data would indicate that we have not been selective in a relative sense, because 18 per cent of the resections were total gastrectomies and 17 per cent were transthoracic cardiectomies, a total of 35 per cent of all resections being of this radical character. We have unhesitatingly removed contiguous organs involved by the gastric cancer, e. g., the spleen, left hepatic lobe, pancreas and transverse colon.

Comparison of Statistical Data

	Dr. Wangensteen and Associates	Drs. Pack and McNeer
	10 Year Period	
Number of gastric cancers	586	683
Operability	76 %	79 %
Resectability	52 %	35 %
Operative mortality Resection	16.6%	Subtotal 12.2% Total 30 %
Operative mortality Gastroenterostomy	24 %	12.5%
Resection survivors 5 years	21.5%	34.7%
Total gastrectomy	10 %	18.3% Radical
Transthoracic cardiectomy	None listed	17.0% procedures

Dr. Waltman Walters, Rochester, Minn.: One of the contributions which Dr. Wangensteen and his associates have made in their paper is that as one's interest in the field of gastric surgery increases, the number of patients subjected to operation increases. The resectability rate will increase, and also the number of patients who undergo resection in relation to the total number examined will increase. Their contribution did a great deal to advance improvement in the treatment of patients with cancer of the stomach with respect to both recognition and more extensive resection. They showed how unsatisfactory were the results when but few operations were performed in comparison to those in which large numbers of patients were operated on by the individual surgeon. The more operations a surgeon performs, the lower will be the mortality rate associated with the type of operation in question and probably, within certain limits, the higher will be the curability rate. Dr. Wangensteen stressed that one of the important factors is early recognition of the lesions. In a large series of cases of cancer of the stomach which my colleagues and I reported in 1939, we were astonished to find (these were cases of proved cancer of the stomach) that a third of the entire group had a history of ulcer and had been treated for suspected ulcers. Of that group of patients with cancer and histories suggestive of ulcer who had been treated according to the suspected diagnosis of benign lesions, 80 per cent manifested an effective clinical response as measured by relief of pain. I am sure that this relief of pain delayed greatly the recognition that a carcinoma of the stomach was present. Sometimes this error is not entirely the fault of the examining physician, for it may be due to errors in interpretation of the roentgenograms of the stomach. In this series to which I have referred, ulcer had been reported in 10 per cent of the malignant lesions; an unspecified type of gastric lesion had been reported in 13 per cent of such lesions; there was an error of 1 per cent where the lesion was not recognized roentgenographically. These figures give rise to considerable speculation, for if the roentgenologist fails to see but 1 per cent of all gastric lesions it emphasizes what Dr. Wangensteen said regarding the desirability of such an examination in the group of persons to whom he referred. Moreover, it illustrates that a roentgenologic report of a gastric ulcer doesn't exclude its being a carcinoma.

HOMOLOGOUS SERUM JAUNDICE IN RECIPIENTS OF POOLED PLASMA

I. JAY BRIGHTMAN, M.D.
and
ROBERT F. KORNS, M.D.
Albany, N. Y.

The ready availability of pooled plasma, whether secured through commercial channels, state departments of health or local blood bank programs, has been a boon to medical practice. However, the fact that plasma may carry a virus capable of inducing hepatitis in the recipient has created a new public health problem of major importance.

The occurrence of homologous serum jaundice in recipients of blood and of blood derivatives has been reported by many investigators in both civilian and military fields. In a recent review Neefe[1] has presented an excellent description of both infectious hepatitis and homologous serum jaundice, and his list of references is extensive. The present study was designed to evaluate the risk of homologous serum jaundice inherent in the utilization of the dried pooled plasma which is now being distributed to meet civilian needs.

TABLE 1.—*Availability of Plasma Recipients for Follow-Up to Determine Incidence of Homologous Serum Jaundice*

Total plasma recipients in random sample	924	
Recipients eliminated	275	
Died within 30 days of transfusion		112
Unable to locate		107
Physician refused to supply information or permit home visit		40
Jaundice attributable to other cause		16
Recipients included in study	649	
Died between 1 and 6 months after transfusion without the development of jaundice		44
Survived 6 months or more, or died from homologous serum jaundice		605

TABLE 2.—*Incidence of Jaundice in Plasma Recipients and Their Household Contacts During Period Between One and Six Months After Transfusion*

	Total	Jaundice Number	Jaundice Percentage
Plasma recipients	649	29	4.5
Household contacts	1,597*	0	0.0

* Includes 56 contacts of the 29 plasma recipients in whom jaundice developed.

The problem was approached through two avenues. Part A: A follow-up study was made on a series of patients six or more months after the administration of pooled plasma to determine the subsequent incidence of homologous serum jaundice and the mortality therefrom. Part B: An investigation was made of a group of persons reported to have died of acute hepatitis in order to determine the number of those in whom previous administration of either plasma or blood may have been responsible.

PART A: FOLLOW-UP OF PLASMA RECIPIENTS

1. *Method of Study.*—The patients included in part A of this study, the follow-up of plasma recipients, had received transfusions with the dried pooled plasma which has been released by the American Red Cross and is now being distributed by the New York State Department of Health. In Upstate New York (New York state exclusive of New York city) physicians are requested to submit reports after the administration of each unit of this plasma, giving the name and other identifying data concerning the recipient, the lot number of the unit, the date of administration, the indication for the transfusion and any resulting immediate reactions. For the purpose of follow-up to determine the incidence of subsequent jaundice, 924 recipients named in these reports were selected at random, the only requirement being that six or more months must have elapsed since the transfusion of plasma.

In the majority of instances a letter was sent to the physician who had attended the patient at the time of the original illness; information was requested with regard to the patient's course subsequent to the transfusion of plasma, and he was asked for permission for the public health nurse to make a home visit. This home visit was a most essential part of the study and accounted for the disclosure of the majority of cases of homologous serum jaundice. Cases in which the physician refused to grant permission for such a visit were eliminated from the study unless he submitted specific evidence that he had full knowledge of the patient's course. In many instances in which the physician allowed the home visit although he indicated that the patient was still under his care and had not developed jaundice, the nurse's visit revealed that jaundice had occurred and that another physician had been in attendance. In such cases the name of the second physician was obtained from the patient or the member of the family who was interviewed, and the clinical data were secured from him.

Another important purpose of the home visit was to obtain data on the incidence of jaundice among the household contacts of the recipient. If infectious hepatitis had occurred among such contacts, it would be difficult to attribute a similar syndrome in the recipient to the administration of plasma.

No home visits were made in instances in which patients were known to have died. When death had occurred between one and six months after the transfusion, a letter was forwarded to the physician who attended the patient during the final illness, to inquire whether any syndrome suggestive of homologous serum jaundice had occurred and, if so, whether it had been a primary or contributory cause of death. Patients dying within one month of the transfusion were eliminated from the study.

The criterion established for the diagnosis of homologous serum jaundice was a bed-confining illness associated with clinical manifestations of acute hepatitis including jaundice, not accounted for by other recognized pathologic conditions and occurring between one and six months after the transfusion. The latter are considered to be the extremes of the incubation period, although this is usually between two and four and one-half months.[1] As most surviving recipients had returned to their homes shortly after the administration of plasma, it was not considered feasible to attempt to detect possible cases of hepatitis without jaundice, a diagnosis difficult to make without laboratory assistance.

2. *Observations.*—Of the 924 recipients in the original sample, there were 649 who proved to be suitable for study and for whom adequate information was obtained (table 1). Home visits were made to 602 of

these persons, the data being secured from the physicians alone in the remaining 47.

The results of the study are presented in table 2. In 29 patients there developed a syndrome characteristic of homologous serum jaundice. In 26 of these, the information with regard to the illness was either supplied directly by the physician or confirmed by him after being first obtained from the patient or his family. In the remaining 3, either there was no physician in attendance or it was not possible to obtain information from him. However, the clinical picture was typical, and the cases were included as examples of homologous serum jaundice.

Table 3.—*Significant Data Concerning Plasma Recipients in Whom Homologous Serum Jaundice Developed*

Case	Age, Years	Sex	Original Illness	Other Blood Therapy	Days Between First Plasma Transfusion and Onset of Jaundice	Remarks
A 1............	52	♀	Carcinoma of breast	None	65	Recovery after severe illness lasting 4 weeks; subjected to laparotomy for possible obstructive jaundice; operative observations compatible with infectious hepatitis
A 2............	73	♀	Abdominal tumor	None	74	Recovery after mild illness lasting 3 weeks
A 3............	63	♂	Nephrolithiasis	None	75	Recovery after moderately severe illness lasting 3 weeeks
A 4............	35	♀	Nephrolithiasis	None	106	Recovery after mild illness lasting 3 weeks
A 5............	76	♂	Carcinoma of prostate	Whole blood	72	Died 14 days after onset of jaundice; physician stated hepatitis was contributory cause of death, carcinoma being primary cause
A 6............	65	♀	Ovarian cyst	None	137	Recovery after illness, which was mild but prolonged for 6 weeks
A 7............	54	♂	Bleeding peptic ulcer	Whole blood	65	Recovery after mild illness lasting 2 weeks
A 8............	51	♀	Chemical pneumonia	Not stated	57	Severe illness necessitating hospitalization; improved in 3 weeks but relapsed 6 weeks later; then confined to bed again for 10 weeks; final recovery
A 9............	23	♂	Laceration of vein	Whole blood	71	Recovery after moderately severe illness lasting 3½ weeks
A 10............	52	♀	Cirrhosis of liver	Whole blood	90	Recovery after mild illness lasting 3 weeks; case included despite original illness with cirrhosis, because of classic incubation period and symptoms and lack of jaundice at any other time before or after; patient followed 6 months after bout of jaundice; had been working for last 5 months; cirrhosis apparently not progressive
A 11............	60	♀	Hyperthyroidism	None	70	Recovery after severe illness lasting 2 weeks
A 12............	71	♀	Uterine prolapse	None	100	Recovery after severe illness lasting 6 weeks
A 13............	67	♀	Brain tumor	None	79	Recovery after moderately severe illness lasting 2 weeks
A 14............	82	♂	Obstruction of urinary tract	Whole blood	132	Recovery after mild illness lasting 4 weeks.
A 15............	28	♂	Peritonitis	None	66	Recovery after severe illness lasting 10 days
A 16............	52	♂	Bleeding peptic ulcer	None	125	Died after severe illness of 26 days; death ascribed to homologous serum jaundice
A 17............	37	♂	Burns	Not stated	155	Recovery after mild illness lasting 10 days
A 18............	62	♂	Intestinal obstruction	Whole blood	67	Recovery after severe illness lasting 10 days
A 19............	53	♂	Cholecystitis	None	58	Recovery after mild illness lasting 1 week; case included despite original illness with cholecystitis because of classic incubation period and symptoms and absence of evidences of biliary tract disease at time of jaundice; jaundice not present at time of original illness
A 20............	30	♀	Parturition	None	102	Recovery after mild illness lasting 2 weeks
A 21............	44	♀	Carcinoma; site unknown	None	120	Recovery after moderately severe illness lasting 8 weeks
A 22............	74	♀	Circulatory collapse	None	113	Recovery after moderately severe illness lasting 8 weeks
A 23............	72	♀	Hernia	None	102	Recovery after moderately severe illness lasting 8 weeks.
A 24............	70	♀	Gangrene of foot	Whole blood	130	Died 4 weeks after onset of jaundice; primary cause of death stated as gangrene, with jaundice possibly a contributory cause
A 25............	75	♂	Incarcerated hernia	None	92	Died 4 days after onset of jaundice; diagnosis, acute yellow atrophy of liver
A 26............	58	♂	Cholecystitis	None	76	Recovery after mild illness lasting 2½ weeks; case included despite original illness with cholecystitis because of classic incubation period and symptoms and absence of evidences of biliary tract disease at time of jaundice; jaundice not present at time of original illness
A 27............	56	♂	Dysentery	None	80	Recovery after moderately severe illness lasting 2½ weeks; patient had history of exposure to carbon tetrachloride over 2 year period, but symptoms and period of time between plasma therapy and onset of illness were considered typical of homologous serum jaundice
A 28............	30	♀	Abruptio placentae	Whole blood	88	Recovery after moderately severe illness lasting 4 weeks
A 29............	72	♂	Malignancy of colon	Whole blood	139	Recovery after moderately severe illness prolonged over 4 months

Based on the entire group of 649 recipients, the incidence of homologous serum jaundice is 4.5 per cent. If one excludes the 44 patients who died between one and six months after transfusion without developing jaundice, on the grounds that they might have done so had they survived longer, the incidence would be 4.8 per cent. In contrast, there were no cases of jaundice reported among the 1,597 household contacts of the recipients. This latter group included 56 persons who were contacts of the recipients in whom jaundice had developed.

Table 3 tabulates the pertinent data concerning each recipient with homologous serum jaundice. The incuion period varied between fifty-seven and one hundred and fifty-five days, which is consistent with the observations of others.[1] Distribution between the sexes was about equal, there being 15 women and 14 men.

The number of patients in the older age group was striking. The median age for the jaundice cases was 57 years compared to 39 years for the recipients in whom jaundice did not develop. The number of cases of jaundice is too small to warrant a breakdown by age into decades. However, a broader division revealed no cases of jaundice in recipients less than 20 years of age, an incidence of 2.2 per cent among the recipients between 20 and 49 and an incidence of 8.7 per cent among those who were 50 years of age or more (table 4). These differences are statistically significant.

TABLE 4.—*Distribution According to Age of Plasma Recipients in Whom Homologous Serum Jaundice Developed*

Age in Years	Total Cases	Homologous Serum Jaundice	
		Number	Percentage
0 to 19	78	0	0.0
20 to 49	319	7	2.2
50 to 89	252	22	8.7
Total	649	29	4.5

In 19 instances the illnesses were considered to have been either mild or moderately severe. Nevertheless, incapacitation in these instances varied from one to six weeks. Six patients who recovered were considered to have been severely ill. On 1 of these (case A 1) a laparotomy had been performed because of the possibility of an obstructiion of the biliary tract. Another (case A 8) had been confined to bed for a total period of thirteen weeks because of a relapse subsequent to initial recovery.

Four deaths occurred. In 2 instances death was attributed directly to homologous serum jaundice (cases A 16 and A 25). In the other 2 patients the clinical data indicated that death was due to an unassociated preexisting illness, with homologous serum jaundice superimposed and playing a contributory role (cases A 5 and A 24). It is impossible to state whether these persons would have survived somewhat longer if hepatitis had not developed. Thus, the fatality rate is at least 6.9 per cent, and possibly 13.8 per cent if the latter 2 cases are included.

3. *Distribution of the Icterogenic Agent Among Various Lots of Plasma.*—Unfortunately, a large proportion of the transfusion reports did not state the lot number of the plasma, thus complicating the study of the distribution of the icterogenic agent. Among the 29 patients with jaundice, the lots of the administered plasma could be identified in only 19. This group had received plasma from 22 different lots. Only 2 of the patients had received plasma from the same lot, indicating that at least 18 of the lots given to the 19 patients were icterogenic.

Further study of the lot which had been given to 2 recipients in whom jaundice developed revealed that it had also been administered to 9 other traceable patients. All 9 had survived six months thereafter, and in none had jaundice developed. The attack rate among the traceable recipients of this lot is therefore about 22 per cent. Twenty of the remaining 21 lots were reported to have been administered to from 1 to 7 other patients without causing jaundice.

A total of 385 identifiable lots were reported as having been given to the entire group of plasma recipients. Of these, 18, or 4.7 per cent, appeared responsible for jaundice. The latter is a minimum figure, as 368 of the identifiable lots had been administered to 5 or less patients, and in view of the apparently low attack rate among recipients many icterogenic lots may have remained undetected because of the small number of trials.

PART B: INVESTIGATION OF RECORDED DEATHS ASCRIBED TO ACUTE HEPATITIS

In the second part of this study, a group of patients who died of some form of acute hepatitis was investigated in order to disclose whether the deaths might be attributed to jaundice associated with plasma or blood therapy. The patients were selected from those for whom physicians had submitted death certificates listing such diagnoses as acute hepatitis, infectious hepatitis, homologous serum jaundice or acute yellow atrophy. The follow-up procedures were carried out by medical personnel of the various district offices of the New York State Department of Health, and the information set down was obtained from the records of the hospital or the attending physician or by interview of the patient's family.

Early in 1946 a random sample of 8 deaths was studied, and it was disclosed that in 3 of these the patients had had transfusion therapy within six months of the onset of the fatal illness. Therefore it was decided to carry out this type of study on all deaths due to hepatitis. From Sept. 16, 1946 through April 15, 1947 a total of 43 such reports was received by the State Department of Health. Investigation of these deaths showed that 12 of the 43 patients had a history of transfusion therapy.

TABLE 5.—*Significant Data Concerning Recorded Cases of Fatal Hepatitis Associated with Transfusion Therapy*

Case	Age in Years	Sex	Original Illness	Transfusion Therapy	Days Between First Transfusion and Onset of Jaundice
B 1*	66	♂	Thigh injury	Plasma	70
B 2*	76	♂	Duodenal ulcer	Plasma	148
B 3*	70	♂	Intestinal obstruction	Plasma	104
B 4	54	♀	Gastric ulcer	Whole blood	61
B 5	5	♀	Unknown	Plasma	144
B 6*	66	♂	Carcinoma of rectum	Plasma	68
B 7*	22	♀	Ovarian abscess	Plasma	73
B 8	48	♀	Compound fracture of legs	Plasma	164
B 9*	20	♀	Postpartum hemorrhage	Plasma	67
B 10*	34	♀	Ectopic pregnancy	Plasma	43
B 11*	18	♀	Burns	Plasma and whole blood	62
B 12	61	♂	Duodenal ulcer	Whole blood	104
B 13*	45	♂	Hydronephrosis; kidney stones	Plasma	47
B 14	74	♀	Hip fracture	Plasma	52
B 15*†	75	♂	Incarcerated hernia	Plasma	92

* Autopsy performed. † Same case as A 25 (table 3).

Thus, 15 of the 51 fatal cases investigated appeared to be associated with previous transfusions of plasma or blood. The pertinent data concerning these cases are recorded in table 5. Clinically, each of the cases met the criterion for the diagnosis of homologous serum jaundice given in part A of this study. Autopsy was performed in 10 instances, and in each the presence of acute hepatitis was established as the primary cause of death.

In 14 instances the illness which existed at the time of the transfusion had completely subsided before the onset of jaundice. The only exception was case B 6, in which the original illness was carcinoma of the rectum. This latter case was among those in which autopsies were performed, and no evidence of hepatic metastasis was demonstrated.

Twelve patients had received pooled plasma only, and 1 patient had been given pooled plasma and whole blood. In each instance the plasma had been obtained from the state department of health. Two patients had received whole blood only. The period between the day of the first transfusion and the onset of jaundice varied from forty-three to one hundred and sixty-four days. Distribution by sex was approximately equal, there being 8 women and 7 men. The median age of the 14 persons was 54 years.

Lot numbers were available for only 6 of the 13 patients who had received plasma, and in none of these was the same lot involved. However, the plasma lot administered in case B 14 was also found accountable for the jaundice which occurred in 3 nonfatal cases. (The latter cases are not among those disclosed in the first part of this study.) Since a total of 7 persons received units of this lot, the attack rate in this group was 57 per cent. Indirect evidence that other lots of plasma may have accounted for multiple cases of infection was indicated by the fact that 3 deaths occurred at one hospital and 2 each at two other hospitals.

COMMENT

A follow-up investigation of a large series of persons who received transfusions with pooled plasma has indicated that this form of therapy carries a significant risk of a serious and possibly fatal complication. The number of persons receiving plasma in Upstate New York is at least 15,000 per year.[2] With a 4.5 per cent incidence of homologous serum jaundice in the recipients of plasma, one can estimate a total of 675 cases annually.

Investigation of recorded deaths due to hepatitis revealed that 12 which were attributable to homologous serum jaundice occurred during a seven month period. This would be an average of 21 deaths per year. This is less than might be expected with a fatality rate of 6.9 per cent, but the rate was based on a small number of deaths. It must also be considered that there may be many cases which are missed because of erroneous reporting.

The incidence of 4.5 per cent is lower than that reported by Spurling, Shone and Vaughan.[3] These authors conducted a similar type of study and followed up patients who had received blood products supplied by the Northwest London Blood Supply Depot. They found 77 frank (7.3 per cent) and 14 doubtful (1.3 per cent) cases of homologous serum jaundice among 1,054 persons followed five months or longer after receiving pooled plasma or serum. (The doubtful cases were those in which the jaundice was most likely attributable to some other cause. In the present study, such cases were eliminated.) However, their cases[3] appear to have been less severe, as only 1 of the frank cases involved serious illness. There were only 2 deaths, and these occurred among the doubtful cases.

Grossman and Saward[4] reported 8 cases of homologous serum jaundice occurring among the recipients of 501 transfusions of commercial pooled plasma at the Northern Permanente Foundation Hospital. This indicates an incidence of over 2 per cent, as the actual number of recipients was less than 501. No follow-up was carried out to determine the occurrence of jaundice in those who remained at home. There was 1 death among the 8 cases, giving a fatality rate of 12.5 per cent.

Scheinberg, Kinney and Janeway[5] have recently reported 11 cases of hepatitis, including 4 fatalities, which were probably due to prior transfusions of plasma or blood. Plasma appeared to be the more likely causative agent. Based on the number of plasma transfusions given at Peter Bent Brigham Hospital over the period during which these persons had originally been hospitalized, the calculated incidence was 1 case of jaundice in every 86 plasma transfusions. However, follow-up was limited to those recipients who were of special interest because of their original disease or who had received plasma already suspected of being icterogenic.

The failure to find any instances of jaundice among the household contacts rules against the possibility that the jaundice occurring in the recipients of plasma might have been due to infectious hepatitis rather than to homologous serum jaundice. The household contacts included large numbers of children, who would be more susceptible to infectious hepatitis were it occurring in the community.[1] In contrast, most of the plasma recipients in whom jaundice developed belonged to the older age group, among whom infectious hepatitis is less likely to occur. Grossman and Saward[4] also observed an absence of secondary cases in the families of patients with homologous serum jaundice. On the other hand, in a study of the families of 77 patients with infectious hepatitis they found that 13, or 17 per cent, of the members had or subsequently acquired jaundice.

At least 9 patients whose cases are included in part A of this study are known to have received whole blood in addition to pooled plasma transfusions, and the possibility does exist that the whole blood may have been responsible for the jaundice in some of these. However, this possibility seems remote in view of several reports which demonstrate a significantly greater incidence of jaundice in recipients of pooled material than in recipients of blood, plasma or serum from individual donors.[6] The most extensive study is that of Spurling, Shone and Vaughan.[3] Although these investigators observed a high incidence of jaundice after transfusions of pooled plasma or serum (vide supra), they were able to discover no frank and only 6 doubtful cases among 891 recipients of whole blood from individual donors.

Part B of the current study brings forth additional evidence with regard to the greater hazard associated with plasma as compared with whole blood. Of 15 deaths ascribed to this disease, 12 persons had received plasma, 2 whole blood and 1 both plasma and blood. A survey made in Upstate New York showed that the ratio of whole blood to plasma transfusions was about 2:1.[2] Yet the ratio of whole blood to plasma transfusions among these 14 cases of homologous serum jaundice was at least 1:4 and possibly 1:6.

The significantly higher incidence of jaundice among plasma recipients who were more than 50 years of age is worthy of comment. In their monograph on icterus subsequent to vaccination against yellow fever, Fox, Manso, Penna and Para[7] have discussed the possibility that lowered hepatic resistance associated with chronic intoxication of the liver or dietary deficiency may serve as a factor in rendering persons susceptible to the icterogenic agent contained in blood products. It is possible that such a factor may have been responsible for the age distribution of cases observed in the present study. In elderly patients hepatic impairment as demonstrated by liver function tests has been shown to be common[8] and latent vitamin deficiency is prevalent.[9]

The possibility was suggested that the size of the transfusions or the use of two or more different lots may have been a factor in determining the recipients in whom jaundice would develop. However, according to the available information, 20 of the 29 jaundice patients had received a single unit of plasma only. The average number of units received by the 29 patients was about 1.5, which is identical with that received by the entire group of plasma recipients.

The frequency with which homologous serum jaundice may occur as a complication of pooled plasma therapy calls for immediate and intensive research aimed at the development of methods for the elimination of the virus. These studies have indicated that the causative agent is present in many different lots of plasma. The exclusion of donors with a history of jaundice and the performance of various laboratory tests on all others will serve to eliminate only a fraction of the asymptomatic carriers of the virus. Single injections of gamma globulin did not lower the incidence of subsequent jaundice among plasma recipients in the military services.[10] Encouraging results were obtained when two injections were given 30 days apart,[11] but the complication was not entirely eliminated and the procedure may be difficult to carry out in civilian life because of the failure of the patients to return. The use of smaller pools may cut down the dissemination of a virus present in any one specimen, but the hazard will still exist. It must also be considered that reduction of the number of specimens per pool below eight will not allow for adequate dilution of isoagglutinins.

Two approaches to this problem offer much promise. First, it has been demonstrated that icterogenic plasma units lose their ability to transmit jaundice after exposure to irradiation with ultraviolet light.[12] The intensive method of applying ultraviolet radiation to bacteria and viruses, as developed by Levinson and his co-workers,[13] may provide a means of irradiating plasma for large-scale processing.

The second possibility is to substitute the albumin fraction for whole plasma in all instances in which such substitution would be clinically warranted.[14] The stability of the albumin fraction as derived by the newer methods of preparation is so great that it can be heated for ten hours at 60 C. in the final container before distribution. This process is believed to inactivate the virus.

Much further study is necessary to demonstrate whether irradiated plasma and the albumin fraction are absolutely virus-free. Also, it will take some time to prepare either material in sufficient quantities to meet all needs. Therefore there would appear to be no point in recalling the pooled plasma being distributed at the present time. However, it must be emphasized that this plasma should be administered only when the clinical indications are absolute, so that the benefits to be derived clearly outweigh the risk of contracting homologous serum jaundice.

SUMMARY

1. Follow-up of 649 patients who received transfusions with dried pooled plasma revealed a subsequent incidence of homologous serum jaundice in 4.5 per cent.
2. The causative agent appears to be widely distributed, but the attack rate is variable.
3. The attack rate was significantly higher among persons who were 50 years of age or more. No relation of the attack rate to the amount of plasma administered could be demonstrated.
4. Investigation of 51 deaths attributed to acute hepatitis revealed 15 cases in which the patients had received transfusion therapy during the six months prior to death. Twelve of these had received plasma only.
5. Twelve deaths attributable to homologous serum jaundice were reported in Upstate New York during a seven month period.
6. Plasma, as well as other forms of transfusion therapy, should be administered only when the clinical indications are absolute, so that the benefits to be derived clearly outweigh the risk of contracting homologous serum jaundice.
7. Immediate, intensive research toward the elimination of the causative agent is imperative.

ADDENDUM.—Subsequent to the submission of this article for publication, a physician belatedly provided information that homologous serum jaundice had developed in a plasma recipient who was originally included in the unlocated group (table 1). The patient was a woman aged 30 who received a transfusion with pooled plasma following an operation for pelvic inflammatory disease. The syndrome of acute hepatitis appeared thirty days later, and the patient was severely ill for a two week period.

ANURIA TREATED BY PERITONEAL IRRIGATION

LAURENCE A. GROSSMAN, M.D.
EDWIN M. ORY, M.D.
and
DAN H. WILLOUGHBY, M.D.
Nashville, Tenn

The treatment of renal failure by the substitution of an artificial kidney has long been considered, and animal experimentation and clinical trials have been carried out. The employment of the peritoneum as a dialyzing membrane constitutes a promising approach to this problem. Its use has not been feasible in the past for several reasons: (1) the lack of a satisfactory lavage fluid, that is, a fluid that would not cause significant disturbance of water and electrolyte balance; (2) the great susceptibility of the peritoneum to infection and the seriousness of such infection, and (3) the technical difficulties with clotting in carrying out the procedure.

Recent developments have largely overcome these difficulties. The work of Abbott and Shea[1] using nephrectomized dogs resulted in the composition of a suitable lavage fluid. Fine, Frank and Seligman[2] improved the technic of peritoneal irrigation in human beings. They successfully treated a patient with uremia and showed that this form of therapy is practical in other cases. Careful asepsis has lessened the danger of peritoneal infection, and new antibiotics are of great value in the prevention and control of infection. Heparin, which reduces the formation of fibrin, has made continuous peritoneal irrigation possible.

From the limited experience thus far reported, peritoneal irrigation is most valuable in renal failure which is potentially reversible and which may be encountered in transfusion reactions, sulfonamide toxication, mercurial poisoning and reflex anuria.

REPORT OF CASE

History.—L. F., a married white woman aged 38, was admitted to the obstetric service of Vanderbilt University Hospital on Sept. 30, 1946, because of difficult labor. This was her third pregnancy. It had been uncomplicated until the month prior to admission, when she began to have headache, vertigo, mild edema of the ankles, nocturia and frequency of urination. During the three days before entry oliguria was noted. There was no history of previous renal disease. Twelve hours before admission labor began with spontaneous rupture of the membranes. Despite hard labor there was no progress.

Physical Examination.—Examination revealed a moderately obese woman in active labor. She was alert and afebrile. The skin and scleras were faintly icteric. The ocular fundi were normal. The heart and lungs were normal. The abdomen was distended with a full term gravid uterus. Tenderness of the costovertebral angle was not present. There was mild edema of the legs below the knees. Examination of the blood revealed a white cell count of 20,000 with a normal differential formula and a hemoglobin level of 12.5 Gm.

Course.—The patient was unable to void at the time of admission. The bladder was catheterized and 30 cc. of bloody urine was obtained. During the following eight hours there were strong regular uterine contractions, but the patient did not progress beyond the first stage of labor. Thom's pelvimetry revealed a mild cephalopelvic disproportion. Because of this disproportion and the history of several vaginal examinations prior to admission a Porro cesarean section was performed with the patient under spinal anesthesia induced by the use of 150 mg. procaine hydrochloride. The patient tolerated the operation well. A viable child was delivered. Blood loss was estimated at 2,000 cc., and a transfusion of 1,500 cc. type O whole blood was administered. At no time did the blood pressure fall to shock levels. The bladder was catheterized at the end of the operation, but no urine was obtained.

After delivery the patient's jaundice increased. On the third hospital day, because of continued anuria cystoscopic examination was performed. The bladder wall appeared edematous and hemorrhagic. Ureteral catheters were passed to each kidney pelvis but no urine was obtained. The renal pelves were irrigated, and the catheters were left in place for four days. Subsequent to this procedure the temperature rose to 101 F., then fell rapidly to normal. There was a rising azotemia and other hematic chemical changes characteristic of renal failure during the eight days following the operation (fig. 1 and table 1). A concomitant fall in the red blood cell count and hemoglobin level occurred during this period. The red cell count fell from 4.65 to 2.12 million per cubic millimeter, and the hemoglobin value fell from 12.5 to 6.0 Gm. per hundred cubic centimeters. The icterus index ranged from 19 to 23. These changes progressed until peritoneal irrigation was instituted.

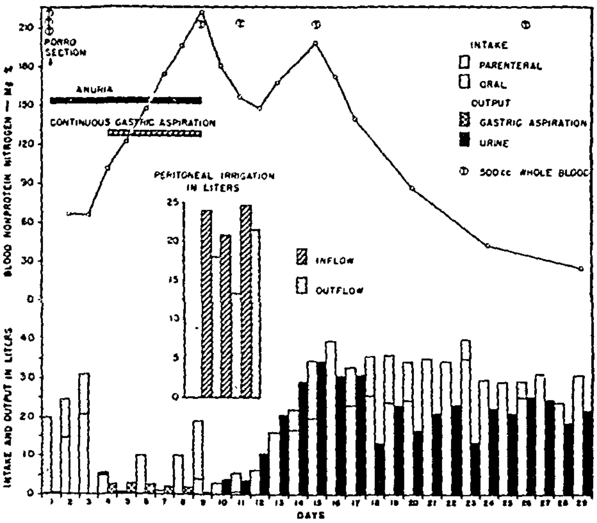

Fig. 1.—Fluid balance and course of azotemia.

Signs of adynamic ileus developed on the fourth hospital day. Continuous gastric aspiration with Wangensteen suction was started with considerable relief of the abdominal distention; however, no peristaltic activity was observed. In the period between the fifth and ninth hospital days the patient received only small amounts of fluid because of the presence of moderate edema (fig. 1). The fluids which were administered consisted of whole blood and 5 per cent dextrose in isotonic sodium chloride solution. Fifty cubic centimeters of 50 per cent dextrose was given on a single occasion.

Irrigation Period.—On the ninth hospital day and the eighth day of anuria the nonprotein nitrogen level had risen to 224 mg. per hundred cubic centimeters, and the patient was drowsy. Peritoneal irrigation was then initiated. Without removing the patient from the bed she was prepared and draped as for a surgical procedure. With the patient under local anesthesia a mushroom catheter was inserted through a small incision in the right upper quadrant and sutured in place. Similarly, a sump drain was inserted into the abdominal cavity through an incision in the left lower quadrant. The irrigation system is illustrated in figure 2.

Surg. **124**: 857-878, 1946.

irrigation fluid had a composition similar to that of solution A of Abbott and Shea,[1] modified only by the addition of penicillin and heparin (table 2). The fluid was administered from liter flasks, and the rate of inflow was adjusted to 1 liter per hour. The volume of outflow was measured hourly. The outflow was spontaneous, no suction being applied. The rate of outflow varied considerably from hour to hour, at times greatly exceeding the volume of inflow and at other times being much less.

After peritoneal irrigation was instituted the course of events changed decidedly for the better. There were no signs of overhydration or underhydration; the blood pressure did not fall significantly, and there was no pulmonary congestion or increase in edema. Drowsiness disappeared, and the patient remained mentally clear. Forty-five cubic centimeters of dark bloody urine was obtained by catheterization during the first day of irrigation. Following this there was a rapid increase in urinary output, as illustrated in figures 1 and 3. During the three day irrigation period, the nonprotein nitrogen level of the blood fell from 224 to 148 mg. per hundred cubic centimeters, with a corresponding decline in the creatinine and serum phosphorus concentrations.

Culture	Sterile	Sterile	Esch. coli A. fecalis

The total nitrogen excretion by urine and lavage fluid is shown in figure 3 and table 3. A total of 71.4 Gm. nitrogen was eliminated in the irrigation fluid, while 4.07 Gm. was excreted in the urine during the same period. The lavage fluid during the first two days of the irrigation remained sterile. On the third day Alcaligenes fecalis and Escherichia coli were cultured. After seventy-two hours the irrigation was discontinued and 0.5 Gm. of streptomycin was instilled intraperitoneally. During the preceding twenty-four hours the urinary output had been 1,080 cc., and it was considered that there was sufficient recovery of renal function to warrant discontinuing the irrigation. On the third day of peritoneal irrigation (eleventh hospital day) for the first time peristalsis was audible and the patient had a spontaneous bowel movement.

Postirrigation Period.—During the three days following discontinuation of peritoneal irrigation the blood nonprotein nitrogen concentration rose to 200 mg. per hundred cubic centimeters; there was a concomitant rise in blood creatinine and serum phosphorus values, and a fall in serum calcium and plasma carbon dioxide. This occurred notwithstanding an increasing urinary output and total nitrogen excretion. After the third postlavage day (fifteenth hospital day) there was a continuous fall in the nonprotein nitrogen level, and other chemical values of the blood reverted gradually to normal. The nonprotein nitrogen was 27 mg. per hundred cubic centimeters on the twenty-ninth hospital day. After the initial fall in the red blood cell count and hemoglobin during the operative procedure, the anemia persisted despite three transfusions. The hemoglobin level ranging between 6 and 7 Gm. per hundred cubic centimeters. There was a leukocytosis; the white cell count varied between 15,000 and 25,000 until the twentieth hospital day, at which time it fell to normal. The edema gradually subsided during the week following peritoneal irrigation.

TABLE 4.—*Summary of Urinalyses*

Hospital Day	Specific Gravity	Albumin	Pyuria	Culture	Therapy
1	1.016	+	++	......	....
2 to 8		Anuria			
9 to 33	1.010 to 1.016	+	++++	P+++	Penicillin, 800,000 units daily 31st to 43d day

67 to 68	1.018	±	+	C+ P++	....

C, Esch. coli and P, p. vulgaris.

Table 4 summarizes the results of daily urinalyses. There was heavy pyuria throughout most of the course. Cultures were persistently positive for Proteus vulgaris. For the first three and a half weeks there was a slight albuminuria. The specific gravity ranged between 1.008 and 1.016. On the twenty-eighth hospital day of the patient there developed an acute pyelonephritis with chills, temperature of 103 F. and frequency and burning on urination. During the next three days there were daily elevations of temperature ranging between 103 and 105.6 F. The strain of P. vulgaris which was isolated from the urine was found to be inhibited in vitro by a concentration of 25 units of penicillin per cubic centimeter and also by streptomycin in the same unit concentration. Penicillin in doses of 100,000 units every three hours was administered for thirteen days. The temperature promptly fell to normal, the frequency and dysuria subsided and the pyuria decreased. However, urine cultures continued to yield a moderate growth of P. vulgaris. Pyuria subsequently increased. The sensitivity of P. vulgaris to penicillin was again determined, and on this occasion the organism was found to be resistant to more than 1,000 units of the drug per cubic centimeter. It was also found to be a potent penicillinase producer. Sulfadiazine in doses of 5 Gm. a day was given between the forty-third and forty-eighth day of hospitalization without beneficial effect.

At the time of discharge on the forty-eighth hospital day the patient was ambulatory; she had no symptoms referable to the urinary tract and was afebrile. The blood chemical determinations were within normal limits and the hemoglobin level was

13 Gm. per hundred cubic centimeters. The Fishberg test showed a maximum urinary concentration of 1.016. Phenolsulphonphthalein excretion totalled 40 per cent in two hours; specimens collected at fifteen, thirty, sixty and one hundred and twenty minutes each contained 10 per cent of the dye. The urea clearance was 49.9 per cent of the average normal value. Moderate pyuria and a heavy bacilluria were still present.

The patient was reexamined on the sixty-seventh and sixty-eighth day after the onset of anuria Except for inconstant nocturia she had been asymptomatic during the three week period. The blood nonprotein nitrogen level was 25 mg. per hundred cubic centimeters. The maximum specific gravity of the urine was 1.018. Phenolsulphonphthalein excretion was 15 per cent at thirty minutes and 20 per cent at one hour, with a total excretion of 35 per cent in one hour. The urea clearance was 55 per cent of the average normal value. There was a slight pyuria, and culture of the urine yielded both P. vulgaris and Esch. coli. Reexamination on the one hundred and fifth day did not reveal any change. The blood nonprotein nitrogen was 32 mg. per hundred cubic centimeters; there was pyuria, and P. vulgaris was present in the urine.

COMMENT

It has not been possible to establish the etiologic basis of the anuria in this case. Likely causes that have been suggested are (1) reflex anuria, (2) cortical necrosis, (3) transfusion reaction and (4) the so-called hepatorenal syndrome. Of these causes it is our opinion that reflex anuria was the etiologic and physiologic mechanism operating in this case. The cephalopelvic disproportion with a prolonged and difficult labor, followed by an operation during which there was manipulation and trauma to the bladder and lower part of the urinary tract constitutes an ideal set of circumstances for the development of this condition. The presence of jaundice and oliguria prior to operative intervention militates against a diagnosis of transfusion reaction. The fact that the patient recovered would cast doubt on cortical necrosis as a cause of the anuria. However, Dieckmann[3] reported a case in which recovery occurred, postulating that necrosis involves only parts of the cortex, with edema and arteriospasm of the remaining cortical area. The presence of jaundice associated with renal failure suggests the possibility of the hepatorenal syndrome. The degree of hepatic failure in this case was insufficient to warrant such a diagnosis.

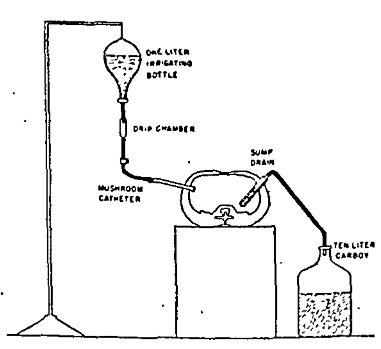

Fig. 2.—Diagram of peritoneal irrigation system.

Our experience with this case demonstrates that peritoneal irrigation is capable of correcting the blood chemical and clinical changes of uremia. It is important to use a fluid that has the proper electrolytic pattern and tonicity. Others[1] have pointed out that failure of this method of treatment in the past has been largely due to difficulty in controlling fluid and electrolyte balance. It will be noted in tables 1 and 2 that an equilibrium was rapidly established between the blood and the irrigation fluid with relation to electrolyte concentrations, and that the blood electrolyte pattern reverted toward normal during therapy.

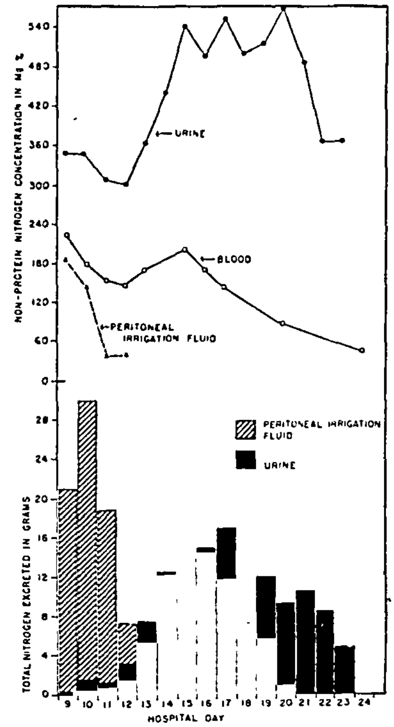

Fig. 3.—Nonprotein nitrogen concentration and nitrogen excretion.

Oliguria had been present for three days before complete renal shutdown occurred. Anuria then persisted for eight days, and the flow of urine began shortly after peritoneal lavage was started. It is impossible to say that the patient would not have survived without peritoneal irrigation, but it is our opinion that this procedure was responsible for her improvement and recovery. The total nitrogen excreted by the kidneys during the irrigation period was 4.07 Gm., while 71.4 Gm. were eliminated by the peritoneum during the same period. For three days after the irrigation had been discontinued the blood nonprotein nitrogen concentration again rose, proving that renal function had not recovered sufficiently to maintain an adequate excretion of nitrogen.

Although peritoneal lavage was begun on the eighth postoperative day and bacteria were found in the lavage fluid on the last day of irrigation, clinical signs of peritonitis did not develop. This was probably because the period of irrigation was brief and antibiotics were used prophylactically.

SUMMARY AND CONCLUSIONS

1. A case of anuria of eight days' duration, which followed a Porro cesarean section, was successfully treated by peritoneal irrigation.

2. It was demonstrated that this is an effective method of eliminating large quantities of nitrogenous products and of restoring blood electrolyte balance and fluid balance to physiologic levels.

A CANCER PREVENTION AND DETECTION CLINIC

LEONARD B. GOLDMAN, M.D.
Long Island, N. Y.

The purpose of this article is to emphasize the importance of the early detection of cancer and to describe the Cancer Prevention and Detection Clinic of the Queens General Hospital. It is hoped that this paper will encourage other hospitals to establish similar clinics.

The first principle in the control of cancer is the recognition that the persistently high mortality is due first, to patients seeking medical aid when in a relatively advanced stage and second, to the failure of the initial examining physician to recognize early miniature malignant growths.

The public, due to the effective educational campaign of the American Cancer Society, has been taught to seek medical advice at an early date and is now prepared for a preventive type of cancer control. But many members of the medical profession are not equipped or lack the time to give the complete examinations necessary to rule out beginning cancer. With the great extension of knowledge in the oncologic field and the tremendous responsibility associated with early diagnosis, cancer has ceased to be a one man job. Group teamwork is essential.

Clinics as they are now organized are concerned chiefly with the obviously ill patient; a person with an early symptom-free carcinoma may be overlooked. Further, hospitals already overburdened with the sick cannot encourage periodic examinations of apparently healthy persons. Yet it is only by such examinations that early carcinomas and precancerous lesions may be detected.

Until more is known about cancer, the most effective step for controlling this disease is the establishment of clinics where apparently healthy persons can be periodically examined. Such clinics would thoroughly study these persons in order (1) to detect early cancer, (2) to help prevent its development by eliminating its precursors, (3) to educate patients to avoid known carcinogenic agents and (4) to expedite the referral of the involved patient for the proper treatment.

The need and value of cancer prevention clinics is further attested to by the following statistics. Elise L'Esperance,[1] who pioneered in this work, examined 4,000 patients in her two clinics (Memorial and Women's Infirmary) and found a 6.5 incidence of cancers. Of these, 98 per cent were early growths which were curable. Of the total number of patients examined, 27 per cent had benign tumors, 30 per cent had other diseases and 36 per cent had no evidence of pathologic conditions. The startling fact was uncovered that cancer was present in 1.5 per cent of patients without any symptoms.

At present these two clinics are so overcrowded that appointments for examinations must be made six months or more in advance, indicating the urgent need for additional clinics.

QUEEN'S GENERAL HOSPITAL CANCER PREVENTION AND DETECTION CLINIC

Organization.—The clinic is under the supervision of the Medical Board of the hospital. The Medical Board has appointed a director of the Clinic (an oncologist) who is responsible for its administration. The staff consists of five specialists: an internist, a surgeon, a gynecologist, an otolaryngologist and a dermatologist. Other personnel consists of two nurses, a laboratory technician, a social worker, a secretary and an orderly.

The clinic is financed by the Queens County Cancer Committee. For admission patients contact the committee, which determines their eligibility and accepts only those entitled to city care. Since the hospital is a municipal one, no charge is made for the examination.

The clinic is held two nights a week from 7 to 9 p. m., and approximately 8 new patients are examined at each session. The social worker (who acts as receptionist), the secretary and the laboratory technician begin their work at 6 p. m. This makes it possible to complete the medical and social histories and to collect the necessary laboratory specimens by 7 o'clock. The patient is then ready for the physical examination. Figures 1, 2 and 3 illustrate pages 1, 2 and 3 of the form used at the clinic.

DIAGNOSES AND RECOMMENDATIONS:

Fig. 3.—Page 3 of the same form (fig. 1). On the line for "Sigmoidoscopy" the revised form reads: (adenoma—refer for Ba enema).

Clinic Routine.—Social History: The size of the family, financial status and veteran status are recorded, and the eligibility of the patient is confirmed.

Medical History: Data, which may be taken by the social worker, are acquired on: (1) the family history with reference to incidence of cancer, including site, for at least two generations; (2) the past medical history, including dental, and (3) the present medical status of the patient.

Physical Examination: Thorough investigation of the body includes nasopharyngeal, laryngeal, vaginal and sigmoidoscopic examinations, roentgenogram of the chest and barium fluoroscopy of the esophagus and stomach.

No Pathologic Condition (45)			

Special Simple Tests: On the first visit special simple tests may be performed if indicated. These include: (1) transillumination of the breast (to differentiate cysts); (2) simple biopsy; (3) aspiration biopsy, and (4) endometrial biopsy.

Special Examinations: If roentgenographic, bronchoscopic, gastroscopic and cystoscopic examinations are symptomatically indicated, the patient is referred to the appropriate clinic.

Laboratory Tests: With the technician present, routine laboratory tests such as a complete blood count, Wassermann, sedimentation rate, urinalysis, vaginal and urethral smears by the Papanicolaou method are done on each patient on the first visit.

Social Service.—The social worker (1) makes the necessary inquiries and investigations with regard to the economic status of the patient; (2) establishes the proper connection between the clinic and the family physician on the one hand, and between the clinic and the patient's family on the other, and (3) follows up patients who have been recommended for treatment so that the clinical work may be statistically evaluated.

Follow-Up.—The patient returns in one week to be seen in conference with the five specialists. Each physician reports his observations. If there are no positive ones, the patient is given an appointment to return in one year if under the age of 40 or in six months if over 40 or if there is a strong family history of cancer. Should any unusual or persistent symptoms occur, return at any time is recommended. If the results of the examination show a pathologic condition—either local or constitutional—the specialist in that field gives a general verbal report of its nature to the patient and, if necessary, allays the patient's fears. The patient is advised to consult the family physician or is referred to the appropriate hospital clinic. The physician, on request, may obtain a detailed record of the examination.

Results.—During the eight month period that the clinic has been in operation 300 patients have been examined and the results are given in the accompanying table.

SUMMARY

The American Cancer Society by its effective educational campaign has laid the groundwork for a preventive type of cancer control. Due to the complexity and variations of the disease, the teamwork of a group is essential. This conviction led to the establishment of the Queens General Hospital Cancer Prevention and Detection Clinic. The organization of this clinic is described, and the results of the examination of the first 300 patients tabulated.

Clinical Notes, Suggestions and New Instruments

ACUTE UREMIA TREATED BY PERITONEAL IRRIGATION

GEORGE J. STREAN, M.D.
MORTON KORENBERG, M.D.
and
JOSEPH C. PORTNUFF, M.D.
Montreal, Canada

Removal of metabolic products by dialysis through the peritoneal membranes is not a new concept in animal experimentation. The idea that anuria and uremia might be treated in this manner was suggested by Abel and his associates[1] as early as 1914. Application of this principle to human beings was first successfully demonstrated by Fine, Frank and Seligman in 1946.[2] A case is reported in which the method described by these investigators was employed.

REPORT OF CASE

D. C., a married white woman aged 25, was admitted to the Montreal Jewish General Hospital on Nov. 28, 1946, complaining of bleeding gums for two months and purpuric spots on her upper and lower extremities for one week.

She first consulted her physician in September 1946, two months prior to her present admission. At that time she was seven months pregnant. On her first visit in September she was decidedly edematous, the edema involving her hands and face as well as her lower extremities. Urinalysis was reported to be normal, and the blood pressure was within normal limits. The fetal heart could not be heard. She had not felt any fetal movements for one week, and it was suspected that the fetus was dead. She was placed on a salt-free diet and put to bed; in about ten days the edema cleared up. In September her gums had begun to bleed, and on the two days prior to her admission the bleeding assumed serious proportions; purpuric spots appeared then for the first time. Hematologic studies before admission revealed: 4,100,000 red blood cells; hemoglobin 80 per cent; numerous platelets, which did not disintegrate normally; a bleeding time seven and one-half minutes; a clotting time over four and one-half hours; prothrombin time 42 seconds (normal 15 to 19 seconds); Rumpel-Leede test negative, and blood grouping A, Rh negative.

The patient had had three previous deliveries in another hospital: the first, in 1940, resulted in a living child after a long labor with postpartum bleeding—she received a transfusion of her husband's blood and had a febrile reaction but recovered after a stormy convalescence; the second pregnancy, in 1942, terminated in a stillbirth; the third delivery, in 1943, was spontaneous and resulted in a normal full term living infant.

The patient was admitted to this hospital with a tentative diagnosis of thrombasthenic purpura complicating pregnancy. On admission the uterus corresponded in size to a seven months gestation although the patient was at term. No fetal heartbeat could be heard, and it was assumed that the fetus was dead. She was bleeding profusely from her gums, and there were large purpuric areas both on the upper and lower extremities.

She was given a transfusion of 500 cc. of citrated whole blood, and immediately afterward had a chill, her temperature then rising to 101.6 F. The donor's blood was first reported to be group A, Rh negative, and compatible, but when it was rechecked after the reaction had occurred, it was Rh positive. Labor started soon afterward, and eleven hours following admission she was delivered spontaneously of a macerated fetus estimated at about seven months gestation. At the time of delivery catheterization yielded only 2 ounces (59 cc.) of grossly bloody urine. After the delivery, in spite of oxytocics and a firmly contracted uterus, she continued to bleed profusely, and the uterus was packed. She was given whole blood, plasma and 5 per cent dextrose in water intravenously; ascorbic acid, vitamin K and calcium gluconate were administered, and the bleeding was finally controlled after twenty-four hours. A hemogram taken thirty-six hours after admission revealed perfectly normal conditions aside from a moderate anemia, and the coagulogram remained normal thereafter.

Following delivery oliguria developed. The urine was grossly bloody and contained numerous granular casts in addition to the cellular elements. During the next three days treatment consisted of the usual measures directed toward stimulating renal function, such as intravenous fluids, diaphoresis, hot poultices to the loins, ureteral catheterization and lavage of the kidney pelves. However, oliguria persisted, the output decreased and azotemia progressed. (See the accompanying chart.)

At this time peritoneal irrigation was instituted according to the technic of Fine, Frank and Seligman. As suggested by these investigators, the composition of both the intravenous and irrigating fluids was modified as the patient's electrolytic balance dictated. Peritoneal irrigation was continued for ten days. During the last twenty-four hours of irrigation the tubes required constant manipulation due to obstruction of both the inflow and outflow tubes, and on the eleventh day the irrigation had to be discontinued. In spite of the use of penicillin, streptomycin and heparin in the irrigating solutions, both infection (minimal) and plugging of the drainage tubes occurred. Fortunately by this time sufficient renal function had returned to enable adequate clearance of the blood.

Two hours before irrigation was discontinued the patient had a generalized convulsive seizure. She was given calcium gluconate and 50 per cent dextrose intravenously, and phenobarbital sodium was administered, but the convulsions recurred at irregular intervals. Because the thought was entertained

A., and Seligman, A. M.: The Treatment of Acute Renal Failure by Peritoneal Irrigation, Ann. Surg. **124**: 857-878 (Nov.) 1946.

that these were caused by electrolytic shift between intracellular and extracellular fluids, isotonic sodium chloride solution was administered intravenously with dramatic cessation of the seizures. This form of therapy was discontinued for thirty-six hours, and the seizures recurred. Again they were controlled promptly with the saline solution. Thereafter, specific therapy consisted of the daily administration of sodium chloride.

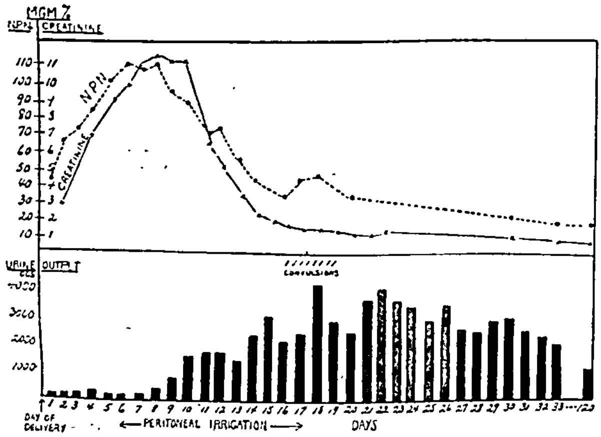
Within twenty-four hours after the institution of peritoneal irrigation, urinary output had doubled. Thereafter the output increased rapidly (see the chart). Abnormal urinary observations disappeared, but the specific gravity of the urine remained low. The patient was discharged thirty-three days after her admission. At that time her blood chemical values were completely normal and her urinary output was approximately 2,400 cc. in twenty-four hours, with a specific gravity of 1.010 to 1.013.

Now, four months after her discharge from hospital, her urinary output is normal in amount, microscopic determinations are within normal limits and the specific gravity varies up to 1.033.

On June 10, 1947, during a laparotomy on this patient for the purpose of removing a large ovarian cyst, we had an opportunity to examine the peritoneal cavity. It was completely free of adhesions.

COMMENT

Lucke has shown recently that cases of acute renal failure due to various causes, such as transfusion reaction, crush syndrome, heat stroke, toxemias of pregnancy, abruptio placentae and blackwater fever, all exhibit essentially the same renal lesion. To this condition he has applied the term "lower nephron nephrosis,"[3] because it is chiefly the lower segment of the nephron which is involved. The lesions vary from focal degeneration to necrosis and disintegration of the epithelium of Henle's loop and the distal convoluted tubules. The distribution of this necrotic and degenerative lesion and the degree of pathologic change are variable.



The treatment of acute uremia by peritoneal irrigation.

In renal shutdown once the initial shock subsides and the renal edema decreases sufficiently, diuresis begins and polyuria develops—the patient passing an unconcentrated glomerular filtrate. Since the renal damage is primarily tubular, some time must elapse before regeneration of damaged epithelium and before adequate or significant concentration of urine can occur.

In the case reported here, diuresis and blood clearance were established soon after the initiation of peritoneal irrigation. It took several months, however, before the urine concentrated to 1.030 and before it was considered safe to take the patient off a regimen of daily salt supplements.

Peritoneal irrigation in the treatment of renal failure can obviously be applied only when the pathologic changes are reversible. With this method it is possible to control the azotemia temporarily, and if the renal damage is not irreparable adequate function of the kidney will be reestablished in ten days to two weeks.

NOTE.—Since this report was written, a case of acute renal failure was successfully treated and reported by Goodyear and Beard.[4]

SUMMARY

1. The successful use of peritoneal irrigation in the treatment of a patient with acute renal failure is reported.
2. The treatment was instituted on the sixth day of oliguria and was maintained continuously for over ten days.
3. In spite of the use of penicillin, streptomycin and heparin in the irrigating solutions, both infection and plugging of the indwelling tubes occurred.
4. Generalized convulsive seizures were promptly controlled by the intravenous use of isotonic sodium chloride solution.
5. Four months after discharge, the results of urinalysis are within normal limits.

Council on Foods and Nutrition

The Council on Foods and Nutrition has authorized publication of the following article. JAMES R. WILSON, *Secretary.*

IMBALANCE AND DIETARY INTERRELATIONSHIPS IN NUTRITION

C. A. ELVEHJEM, Ph.D.
Madison, Wis.
and
WILLARD H. KREHL, Ph.D.
New Haven, Conn.

One might define, as the optimum goal of the nutritional biochemist, the development of a diet which supplies all nutrients in respect to kind and amount and in proper state of combination for all physiologic processes from conception to the death of the organism. In addition, the adequate diet must contain a minimum of injurious (toxic) factors. Such a diet would indeed be balanced, and any important deviation downward from the proper amount of a nutrient would lead to one well known kind of imbalance, reflected as deficiency disease. Since much has been written concerning this kind of imbalance, it will be considered here only incidentally.

It is primarily when and where a variety and abundance of foodstuffs are available that one can apply the criteria of a balanced diet as far as knowledge permits. Any situation, whether due to economic, political, geographic or climatic reasons, which limits the food supply, both as to choice and as to amount, obviously allows a restricted application of the concept of a "balanced diet." Under such conditions the most compelling desire of the organism is for calories. Whether the source of calories supplies the "essential factors" is largely a matter of happenstance. It is perhaps a fortuitous physiologic fact that the requirement for some factors, such as vitamin B_1, is somewhat reduced under conditions of caloric restriction. When, however, the sources of calories are limited primarily to a single food material such as polished rice or corn, we see "nutritional imbalance" at its worst, with large numbers of people afflicted with beriberi and pellagra respectively.

It is pertinent to consider for a moment the basis on which our present criteria for a balanced diet were arrived at. Most of the fundamental knowledge concerning the requirements for the various known (and as yet some unknown factors) has been obtained through numerous and laborious studies with experimental animals. In addition the clinician has made invaluable contributions by translating these experimental observations into practical studies with human patients. As data accumulated from animal feeding experiments it became obvious that the quality of a ration could not be accurately ascertained on the basis of its chemical composition alone. It became further evident that requirements for specific factors changed with alterations in diet composition and that many needed factors existed which were beyond the scope of available analytical chemical methods. The employment of highly purified rations gave perhaps the greatest impetus to the search for an elucidation of unknown vitamins, until now it is proudly stated (although always with some reservation) that at least the qualitative nutritional requirements of certain species are known. Several important lessons can be gleaned from the accumulated experimental data and are worth enumerating: (*a*) the effectiveness of nutrition in maintaining optimum health depends on the inclusion in the diet of the least known as well as the best known nutrient, (*b*) it is desirable to employ numerous species of animals in nutritional research, since nutritional requirements vary both in kind and in amount from species to species and (*c*) the application of accumulated experience to problems of human nutrition will certainly be on a firmer basis when the nutritional requirements of experimental animals are known.

[4] Goodyear, W. E., and Beard, D. E.: The Successful Treatment of Acute Renal Failure by Peritoneal Irrigation, J. A. M. A. **133**: 1208-1210 (April 19) 1947.

One of the important and practical achievements in nutrition is the development of the tables of recommended dietary allowances[1] prepared by the Food and Nutrition Board of the National Research Council. These tables were developed largely by the application of "cooperant reason" to the numerous published nutritional observations on animals and human beings. It will be noted that the board uses the term recommended allowances rather than standards to "avoid any implication of finality." It is difficult to make an adequate evaluation of the service that this board has rendered, since in addition to establishing certain "yardsticks" of good nutrition it has intelligently focused attention on the ever important problem of "adequate nutrition for all." That such attention is important is sadly apparent in the continued evidence for "inadequate diets and nutritional deficiencies" in the United States.[2]

Although "synthetic diets" have proved invaluable in determining what and about how much vitamin, amino acid or fatty acid is required by various animals, it is becoming increasingly apparent that the requirements for these specific materials both qualitatively and quantitatively can be definitely altered when fed as components of a foodstuff. That man can derive his nutrition, at least for a short time, on a synthetic diet is known;[3] however, for the most part man's diet is composed of natural materials, and for this reason a new approach to nutritional research awaits further investigation, namely the study of the effect of these various materials and the kind and percentage of dietary components on the requirement of those factors which are required for the most part in relatively small amounts.

One potentially important aspect of the matter of altered vitamin requirement induced by natural materials is indicated by Woolley's[4] studies on certain relationships of chemical structure to biologic activity. It has been shown that certain chemical substances which have a structural relationship to various required biologic compounds may cause, when administered, specific signs of deficiency diseases which can be "reversed by the metabolites in question when given in adequate amounts." Extensive evidence for the natural existence for such "inhibitors" is not available, but this may be due primarily to lack of knowledge and experimental technics for demonstrating their existence. That such materials can exist under certain specified conditions is demonstrated by the vitamin K deficiency caused by dicumarin when spoiled sweet clover hay is eaten by cattle. It must be emphasized that the activity of these "anti compounds" is presumably due to the fact that they closely resemble the required biologic compound in chemical structure. Whether all "inhibitor" materials operate via the mechanism postulated by Woolley remains to be proved.

Another general factor which may result in imbalance in nutrition is the presence of natural toxicants in food. Materials in food, whether naturally present or as the result of processing, such as fluorine, selenium, lead, arsenic and copper, appear high on the list of intoxicants which may seriously impair the physiology of the organism when they are ingested at too high a level. The presence of the toxic agent gossypol in certain cottonseed meals must be considered when this feed is employed in animal rations. Under the same category must be placed certain wheat glutens and wheat products which are known to produce the disease known as canine hysteria.[5] It has been shown recently, however, that wheat flour is effective in producing this disease as a result of its treatment with agene (NCl_3), a common agent for bleaching and improving flour.[6] Whether agene induces canine hysteria directly or because of changes it produces in the wheat gluten is not certain; nor is it certain that additional factors are not involved.

The fact that the consumption of certain legumes such as fava beans, djenkol beans and lathyrus peas produce untoward results is well known and need not be discussed further.

While the nutritional imbalance and biochemical defects due to such intoxicants can be readily produced, explanations of their mechanisms are not well known. Even less understood are the changes in requirement and production of deficiencies and altered physiology which may result from seemingly innocuous modifications of such factors as the type of carbohydrate in the ration, balance of inorganic elements, amount and kind of protein or amino acid(s), qualitative and quantitative changes of fat and fatty acids in the diets, and general vitamin level. In addition one must consider the interrelationships known to exist between nutrients.

The foregoing factors are known to induce "imbalances" in nutrition which are considerably more difficult to explain than the mere omission of a specific required substance, and these somewhat subtle changes will be considered at some length.

MINERAL IMBALANCE

Because of the importance of calcium and phosphorus in nutrition, some of the significant factors concerning their availability as affected by diet are worthy of

6. Mellanby, Edward: Diet and Canine Hysteria: Experimental Production, Brit. M. J. **2**: 885 (Dec. 14) 1946.

consideration. Of the important factors which favorably influence the absorption and utilization of calcium, magnesium and phosphorus, an acid reaction in the intestine ranks high in importance.

That vitamin D is important in calcium utilization may be explained at least in part by the little understood fact that it tends to favor the production of an acid p_H in the intestine. In this connection another recently elaborated role of vitamin D is the observation[7] that it has a favorable influence on the utilization of the phosphorus of phytin, the availability of which has been the subject of considerable controversy.

Moderate quantities of dietary fat may also play a favorable role in promoting an acid intestinal reaction. Another dietary component which promotes such a reaction is lactose, which probably mediates its influence through the establishment of an aciduric bacterial flora. Is it not interesting that when the need for calcium and phosphorus assimilation is greatest (i. e. the growing child), the major, normal dietary component is milk, which is not only a good source of these minerals but contains lactose and is high in fat? Dextrin and corn starch also have an effect similar to but less than lactose.

Another important consideration concerning the possible imbalance of diets due to minerals is the significance of the calcium-phosphorus ratio. From the considerable work that has been done on this subject, it may be concluded that both calcium and phosphorus may be lost from the body and excreted in the event of any decided abnormality of the calcium: phosphorus ratio. There is considerable variation in opinion as to just what the optimum ratio should be, and it certainly varies with the nutritive requirement at different ages (i. e.) from 1.5:1 to 2:1 for infants, to about 1:1 for older children.[8] Milk which may be considered a sound basis for good nutrition has a Ca:P ratio of about 1.2:1.

Other factors which may adversely affect calcium utilization are excessive amounts of magnesium in the diet and the well known calcium combining action of the oxalate in certain foods.

In considering the other minerals which may interfere with phosphorus utilization one could conclude that certain cations such as iron and manganese for practical examples, which form insoluble phosphate compounds in the intestinal tract, may, if fed in sufficient concentration, lead to impaired phosphorus utilization. Likewise excesses of phosphorus in the diet can interfere with the utilization of these cations. McCance[9] for instance found that both phosphate and phytin interfered perceptibly with iron absorption, although the effect of phosphate was not as great as that of phytate.

In relation to calcium utilization, it was shown[10] that diets high in protein notably favored the absorption of calcium and also resulted in increased magnesium absorption. This observation might have significance in locations where protein comprises a major portion of the diet, and calcium intake is limited.

The effect of a general mineral imbalance is well illustrated in the recent observation[11] that a partial substitution of casein with whey protein in a formula simulating human milk resulted in a retardation of rat growth. This result was not in accord with the well known superior biologic value of lactalbumin (in whey) over casein. This discrepancy was made clear however when, by dialysis of the whey, its minerals were removed and more favorable growth ensued. When the minerals which had been dialyzed from the whey were ashed and reintroduced in the ration, poor growth again resulted.

INFLUENCE OF FATS

It has been indicated that dietary fat may assist in calcium and phosphorus utilization by favoring a more acid reaction in the intestinal tract. In addition it is increasingly apparent that fats may have other important roles in nutrition beyond the fact that they assist in the absorption of and act as carriers for the fat soluble vitamins. The human body can utilize 93 to 98 per cent of most common fats and it can tolerate quantities of fat equivalent to at least a third of the average daily energy consumption.[12] No definite opinion has been crystallized as to the optimum level of dietary fat; suggestions have been made favoring levels just sufficient to supply the essential fatty acids up to an amount equivalent to 25 or 30 per cent of the daily intake. Even greater divergence of opinion is evident concerning the type of fat which should be employed in the diet. The numerous controversial observations[13] regarding the nutritional superiority of butter fat over certain vegetable fats are sufficient to illustrate this point. The recent report[14] that vaccenic acid (C18, Δ 11, 12 elaidinic acid), present in summer butter, has growth promoting properties offers the most concrete evidence to date in support of butterfat superiority for rat growth. It remains to be seen whether this observation will be confirmed or lead to further controversy.

Boutwell and his associates[15] in extensive experiments have consistently observed that when lactose is used as the sole carbohydrate, or when the general level of B complex vitamins is employed at a comparatively low level, butterfat is superior to corn oil in effecting rat growth. Even greater growth differences were evident when younger rats (less than 21 days old) were used at the start of the experiment.[16] Certainly, some of the observed differences between butterfat and corn oil may be explained on the different effects of these respective fats on the intestinal flora.

To present the other side of this controversy, Deuel and his associates[17] observed that "if fat per se is required for fertility and pregnancy, its requirement may be equally satisfied by the various vegetable fats as by butter. From the standpoint of lactation, as judged by the survival of the litter and the weight of the young at weaning time, the different fats were also equally effective." Interesting as this problem is, its final solution can be reached only through further research.

Perhaps more pertinent to the topic under consideration is the relationship between dietary fats and other nutrients. For example, the presence of rancid fat in the diet produces some interesting effects which deserve mention. From the accumulated literature on this subject it appears that there is significant destruction of vitamin A as a result of rancid dietary fat. This destruction seems to be associated with intense peroxide formation, although it has been concluded [18] that intermediates of fatty acid peroxidation are the active agents involved and not the peroxides themselves. It has been shown too [19] that oxidative changes which accompany the development of rancidity in unsaturated fats destroy vitamin E.

That high fat diets exhibit a striking effect on the requirement of certain members of the B complex is well known. Mannering [20] has shown for example that fat at a level of 25 and 40 per cent of the diet materially increased the riboflavin requirement of the rat. This effect may be mediated through the impairment of riboflavin synthesis by intestinal bacteria as an unfavorable result of the high fat level. It is interesting to note in this connection that milk, a high fat food, is one of the richest natural sources of riboflavin.

The thiamine sparing action of fat has been adequately reviewed,[21] but in view of recent experiments [22] this sparing action must be considered with somewhat greater reservation, since it can be shown that the young, growing rat develops the typical symptoms of polyneuritis actually more clearly on B_1 deficient high fat diets than on isocaloric carbohydrate diets. This observation is certainly more consistent with the increasing evidence in support of the tricarboxylic acid cycle as a pathway for the oxidation of fatty acids as well as carbohydrate. This being the case, thiamine should be as important in fat metabolism as in carbohydrate metabolism.

Evidence is also available [22] which indicates that the growth of rats on pantothenic acid deficient diets can be greatly improved by the isocaloric replacement of the carbohydrate of the diet with fat. In addition, the difference obtained is greater when the protein level of the diet is high than when it is low.
